1.1 Introduction

WebAssembly (abbreviated Wasm²) is a *safe, portable, low-level code format* designed for efficient execution and compact representation. Its main goal is to enable high performance applications on the Web, but it does not make any Web-specific assumptions or provide Web-specific features, so it can be employed in other environments as well.

WebAssembly is an open standard developed by a [W3C Community Group](#)¹.

This document describes version 3.0 (Draft 2025-08-05) of the [core](#) WebAssembly standard. It is intended that it will be superseded by new incremental releases with additional features in the future.

1.1.1 Design Goals

The design goals of WebAssembly are the following:

- Fast, safe, and portable *semantics*:
 - **Fast**: executes with near native code performance, taking advantage of capabilities common to all contemporary hardware.
 - **Safe**: code is validated and executes in a memory-safe³, sandboxed environment preventing data corruption or security breaches.
 - **Well-defined**: fully and precisely defines valid programs and their behavior in a way that is easy to reason about informally and formally.
 - **Hardware-independent**: can be compiled on all modern architectures, desktop or mobile devices and embedded systems alike.
 - **Language-independent**: does not privilege any particular language, programming model, or object model.
 - **Platform-independent**: can be embedded in browsers, run as a stand-alone VM, or integrated in other environments.
 - **Open**: programs can interoperate with their environment in a simple and universal manner.

² A contraction of “WebAssembly”, not an acronym, hence not using all-caps.

¹ <https://www.w3.org/community/webassembly/>

³ No program can break WebAssembly’s memory model. Of course, it cannot guarantee that an unsafe language compiling to WebAssembly does not corrupt its own memory layout, e.g. inside WebAssembly’s linear memory.

- Efficient and portable *representation*:
 - **Compact**: has a binary format that is fast to transmit by being smaller than typical text or native code formats.
 - **Modular**: programs can be split up in smaller parts that can be transmitted, cached, and consumed separately.
 - **Efficient**: can be decoded, validated, and compiled in a fast single pass, equally with either just-in-time (JIT) or ahead-of-time (AOT) compilation.
 - **Streamable**: allows decoding, validation, and compilation to begin as soon as possible, before all data has been seen.
 - **Parallelizable**: allows decoding, validation, and compilation to be split into many independent parallel tasks.
 - **Portable**: makes no architectural assumptions that are not broadly supported across modern hardware.

WebAssembly code is also intended to be easy to inspect and debug, especially in environments like web browsers, but such features are beyond the scope of this specification.

1.1.2 Scope

At its core, WebAssembly is a *virtual instruction set architecture (virtual ISA)*. As such, it has many use cases and can be embedded in many different environments. To encompass their variety and enable maximum reuse, the WebAssembly specification is split and layered into several documents.

This document is concerned with the core ISA layer of WebAssembly. It defines the instruction set, binary encoding, validation, and execution semantics, as well as a textual representation. It does not, however, define how WebAssembly programs can interact with a specific environment they execute in, nor how they are invoked from such an environment.

Instead, this specification is complemented by additional documents defining interfaces to specific embedding environments such as the Web. These will each define a WebAssembly *application programming interface (API)* suitable for a given environment.

1.1.3 Security Considerations

WebAssembly provides no ambient access to the computing environment in which code is executed. Any interaction with the environment, such as I/O, access to resources, or operating system calls, can only be performed by invoking [functions](#) provided by the [embedder](#) and imported into a WebAssembly [module](#). An embedder can establish security policies suitable for a respective environment by controlling or limiting which functional capabilities it makes available for import. Such considerations are an embedder's responsibility and the subject of [API definitions](#) for a specific environment.

Because WebAssembly is designed to be translated into machine code running directly on the host's hardware, it is potentially vulnerable to side channel attacks on the hardware level. In environments where this is a concern, an embedder may have to put suitable mitigations into place to isolate WebAssembly computations.

1.1.4 Dependencies

WebAssembly depends on two existing standards:

- [IEEE 754](#)⁴, for the representation of [floating-point data](#) and the semantics of respective [numeric operations](#).
- [Unicode](#)⁵, for the representation of import/export [names](#) and the [text format](#).

However, to make this specification self-contained, relevant aspects of the aforementioned standards are defined and formalized as part of this specification, such as the [binary representation](#) and [rounding](#) of floating-point values, and the [value range](#) and [UTF-8 encoding](#) of Unicode characters.

⁴ <https://ieeexplore.ieee.org/document/8766229>

⁵ <https://www.unicode.org/versions/latest/>

Note

The aforementioned standards are the authoritative source of all respective definitions. Formalizations given in this specification are intended to match these definitions. Any discrepancy in the syntax or semantics described is to be considered an error.

1.2 Overview

1.2.1 Concepts

WebAssembly encodes a low-level, assembly-like programming language. This language is structured around the following concepts.

Values

WebAssembly provides only four basic *number types*. These are integers and IEEE 754⁶ numbers, each in 32 and 64 bit width. 32-bit integers also serve as Booleans and as memory addresses. The usual operations on these types are available, including the full matrix of conversions between them. There is no distinction between signed and unsigned integer types. Instead, integers are interpreted by respective operations as either unsigned or signed in two's complement representation.

In addition to these basic number types, there is a single 128 bit wide vector type representing different types of packed data. The supported representations are four 32-bit, or two 64-bit IEEE 754⁷ numbers, or different widths of packed integer values, specifically two 64-bit integers, four 32-bit integers, eight 16-bit integers, or sixteen 8-bit integers.

Finally, values can consist of opaque *references* that represent pointers towards different sorts of entities. Unlike with other types, their size or representation is not observable.

Instructions

The computational model of WebAssembly is based on a *stack machine*. Code consists of sequences of *instructions* that are executed in order. Instructions manipulate values on an implicit *operand stack*⁸ and fall into two main categories. *Simple* instructions perform basic operations on data. They pop arguments from the operand stack and push results back to it. *Control* instructions alter control flow. Control flow is *structured*, meaning it is expressed with well-nested constructs such as blocks, loops, and conditionals. Branches can only target such constructs.

Traps

Under some conditions, certain instructions may produce a *trap*, which immediately aborts execution. Traps cannot be handled by WebAssembly code, but are reported to the outside environment, where they typically can be caught.

Functions

Code is organized into separate *functions*. Each function takes a sequence of values as parameters and returns a sequence of values as results. Functions can call each other, including recursively, resulting in an implicit call stack that cannot be accessed directly. Functions may also declare mutable *local variables* that are usable as virtual registers.

Tables

A *table* is an array of opaque values of a particular *reference type*. It allows programs to select such values indirectly through a dynamic index operand. Thereby, for example, a program can call functions indirectly through a dynamic index into a table. This allows emulating function pointers by way of table indices.

Linear Memory

A *linear memory* is a contiguous, mutable array of raw bytes. Such a memory is created with an initial size but can be grown dynamically. A program can load and store values from/to a linear memory at any byte address (including unaligned). Integer loads and stores can specify a *storage size* which is smaller than the

⁶ <https://ieeexplore.ieee.org/document/8766229>

⁷ <https://ieeexplore.ieee.org/document/8766229>

⁸ In practice, implementations need not maintain an actual operand stack. Instead, the stack can be viewed as a set of anonymous registers that are implicitly referenced by instructions. The *type system* ensures that the stack height, and thus any referenced register, is always known statically.

size of the respective value type. A trap occurs if an access is not within the bounds of the current memory size.

Modules

A WebAssembly binary takes the form of a *module* that contains definitions for functions, tables, and linear memories, as well as mutable or immutable *global variables*. Definitions can also be *imported*, specifying a module/name pair and a suitable type. Each definition can optionally be *exported* under one or more names. In addition to definitions, modules can define initialization data for their memories or tables that takes the form of *segments* copied to given offsets. They can also define a *start function* that is automatically executed.

Embedder

A WebAssembly implementation will typically be *embedded* into a *host* environment. This environment defines how loading of modules is initiated, how imports are provided (including host-side definitions), and how exports can be accessed. However, the details of any particular embedding are beyond the scope of this specification, and will instead be provided by complementary, environment-specific API definitions.

1.2.2 Semantic Phases

Conceptually, the semantics of WebAssembly is divided into three phases. For each part of the language, the specification specifies each of them.

Decoding

WebAssembly modules are distributed in a *binary format*. *Decoding* processes that format and converts it into an internal representation of a module. In this specification, this representation is modelled by *abstract syntax*, but a real implementation could compile directly to machine code instead.

Validation

A decoded module has to be *valid*. Validation checks a number of well-formedness conditions to guarantee that the module is meaningful and safe. In particular, it performs *type checking* of functions and the instruction sequences in their bodies, ensuring for example that the operand stack is used consistently.

Execution

Finally, a valid module can be *executed*. Execution can be further divided into two phases:

Instantiation. A module *instance* is the dynamic representation of a module, complete with its own state and execution stack. Instantiation executes the module body itself, given definitions for all its imports. It initializes globals, memories and tables and invokes the module's start function if defined. It returns the instances of the module's exports.

Invocation. Once instantiated, further WebAssembly computations can be initiated by *invoking* an exported function on a module instance. Given the required arguments, that executes the respective function and returns its results.

Instantiation and invocation are operations within the embedding environment.

2.1 Conventions

WebAssembly is a programming language that has multiple concrete representations (its [binary format](#) and the [text format](#)). Both map to a common structure. For conciseness, this structure is described in the form of an *abstract syntax*. All parts of this specification are defined in terms of this abstract syntax.

2.1.1 Grammar Notation

The following conventions are adopted in defining grammar rules for abstract syntax.

- Terminal symbols (atoms) are written in sans-serif font or in symbolic form: `i32`, `nop`, `→`, `[,]`.
- Nonterminal symbols are written in italic font: *valtype*, *instr*.
- A^n is a sequence of $n \geq 0$ iterations of A .
- A^* is a possibly empty sequence of iterations of A . (This is a shorthand for A^n used where n is not relevant.)
- A^+ is a non-empty sequence of iterations of A . (This is a shorthand for A^n where $n \geq 1$.)
- $A^?$ is an optional occurrence of A . (This is a shorthand for A^n where $n \leq 1$.)
- Productions are written $sym ::= A_1 \mid \dots \mid A_n$.
- Large productions may be split into multiple definitions, indicated by ending the first one with explicit ellipses, $sym ::= A_1 \mid \dots$, and starting continuations with ellipses, $sym ::= \dots \mid A_2$.
- Some productions are augmented with side conditions, “if *condition*”, that provide a shorthand for a combinatorial expansion of the production into many separate cases.
- If the same meta variable or non-terminal symbol appears multiple times in a production, then all those occurrences must have the same instantiation. (This is a shorthand for a side condition requiring multiple different variables to be equal.)

2.1.2 Auxiliary Notation

When dealing with syntactic constructs the following notation is also used:

- ϵ denotes the empty sequence.
- $|s|$ denotes the length of a sequence s .
- $s[i]$ denotes the i -th element of a sequence s , starting from 0.

- $s[i : n]$ denotes the sub-sequence $s[i] \dots s[i + n - 1]$ of a sequence s .
- $s[[i] = A]$ denotes the same sequence as s , except that the i -th element is replaced with A .
- $s[[i : n] = A^n]$ denotes the same sequence as s , except that the sub-sequence $s[i : n]$ is replaced with A^n .
- $s_1 \oplus s_2$ denotes the sequence s_1 concatenated with s_2 ; this is equivalent to $s_1 s_2$, but used for clarity.
- $\bigoplus s^*$ denotes the flattened sequence, formed by concatenating all sequences s_i in s^* .
- $A \in s$ denotes that A is a member of the sequence s , that is, s is of the form $s_1 A s_2$ for some sequences s_1, s_2 .

Moreover, the following conventions are employed:

- The notation x^n , where x is a non-terminal symbol, is treated as a meta variable ranging over respective sequences of x (similarly for x^* , x^+ , $x^?$).
- When given a sequence x^n , then the occurrences of x in an iterated sequence $(\dots x \dots)^n$ are assumed to denote the individual elements of x^n , respectively (similarly for x^* , x^+ , $x^?$). This implicitly expresses a form of mapping syntactic constructions over a sequence.
- $e^{i < n}$ denotes the same sequence as e^n , but implicitly also defines i^n to be the sequence of values 0 to $(n - 1)$.

Note

For example, if x^n is the sequence $a b c$, then $(f(x) + 1)^n$ denotes the sequence $(f(a) + 1) (f(b) + 1) (f(c) + 1)$. The form $e^{i < n}$ additionally gives access to an index variable inside the iteration. For example, $(f(x) + i)^{i < n}$ denotes the sequence $(f(a) + 0) (f(b) + 1) (f(c) + 2)$.

Productions of the following form are interpreted as *records* that map a fixed set of fields field_i to “values” A_i , respectively:

$$r ::= \{ \text{field}_1 A_1, \text{field}_2 A_2, \dots \}$$

The following notation is adopted for manipulating such records:

- Where the type of a record is clear from context, empty fields with value ϵ are often omitted.
- $r.\text{field}$ denotes the contents of the field component of r .
- $r[\text{field} = A]$ denotes the same record as r , except that the value of the field component is replaced with A .
- $r[\text{field} = \bigoplus A^*]$ denotes the same record as r , except that A^* is appended to the sequence value of the field component, that is, it is short for $r[\text{field} = r.\text{field} \oplus A^*]$.
- $r_1 \oplus r_2$ denotes the composition of two identically shaped records by concatenating each field of sequences point-wise:

$$\{ \text{field}_1 A_1^*, \text{field}_2 A_2^*, \dots \} \oplus \{ \text{field}_1 B_1^*, \text{field}_2 B_2^*, \dots \} = \{ \text{field}_1 (A_1^* \oplus B_1^*), \text{field}_2 (A_2^* \oplus B_2^*), \dots \}$$

- $\bigoplus r^*$ denotes the composition of a sequence of records, respectively; if the sequence is empty, then all fields of the resulting record are empty.

The update notation for sequences and records generalizes recursively to nested components accessed by “paths” $pth ::= ([i] \mid .\text{field})^+$:

- $s[[i] pth = A]$ is short for $s[[i] = s[[i][pth = A]]]$,
- $r[\text{field} pth = A]$ is short for $r[\text{field} = r.\text{field}[pth = A]]$.

2.1.3 Lists

Lists are bounded sequences of the form A^n (or A^*), where the A can either be values or complex constructions. A list can have at most $2^{32} - 1$ elements.

$$\text{list}(X) ::= X^* \quad \text{if } |X^*| < 2^{32}$$

2.2 Values

WebAssembly programs operate on primitive numeric *values*. Moreover, in the definition of programs, immutable sequences of values occur to represent more complex data, such as text strings or other vectors.

2.2.1 Bytes

The simplest form of value are raw uninterpreted *bytes*. In the abstract syntax they are represented as hexadecimal literals.

$$\text{byte} ::= 0x00 \mid \dots \mid 0xFF$$

Conventions

- The meta variable b ranges over bytes.
- Bytes are sometimes interpreted as natural numbers $n < 256$.

2.2.2 Integers

Different classes of *integers* with different value ranges are distinguished by their *bit width* N and by whether they are *unsigned* or *signed*.

$$\begin{aligned} uN &::= 0 \mid \dots \mid 2^N - 1 \\ sN &::= -2^{N-1} \mid \dots \mid -1 \mid 0 \mid +1 \mid \dots \mid +2^{N-1} - 1 \\ iN &::= uN \end{aligned}$$

The class i defines *uninterpreted* integers, whose signedness interpretation can vary depending on context. In the abstract syntax, they are represented as unsigned values. However, some operations [convert](#) them to signed based on a two's complement interpretation.

Note

The main integer types occurring in this specification are [us](#), [u32](#), [u64](#), and [u128](#). However, other sizes occur as auxiliary constructions, e.g., in the definition of [floating-point](#) numbers.

Conventions

- The meta variables m, n, i, j range over integers.
- Numbers may be denoted by simple arithmetics, as in the grammar above. In order to distinguish arithmetics like 2^N from sequences like $(1)^N$, the latter is distinguished with parentheses.

2.2.3 Floating-Point

Floating-point data represents 32 or 64 bit values that correspond to the respective binary formats of the [IEEE 754](#)⁹ standard (Section 3.3).

Every value has a *sign* and a *magnitude*. Magnitudes can either be expressed as *normal* numbers of the form $m_0 \cdot m_1 m_2 \dots m_m \cdot 2^e$, where e is the exponent and m is the *significand* whose most significant bit m_0 is 1, or as a *subnormal* number where the exponent is fixed to the smallest possible value and m_0 is 0; among the subnormals

⁹ <https://ieeexplore.ieee.org/document/8766229>

are positive and negative zero values. Since the significands are binary values, normals are represented in the form $(1 + m \cdot 2^{-M}) \cdot 2^e$ in the abstract syntax, where M is the bit width of m ; similarly for subnormals.

Possible magnitudes also include the special values ∞ (infinity) and nan (*NaN*, not a number). NaN values have a *payload* that describes the mantissa bits in the underlying [binary representation](#). No distinction is made between signalling and quiet NaNs.

$$\begin{aligned} fN &::= +fmagN \mid -fmagN \\ fmagN &::= \begin{array}{ll} (1 + m \cdot 2^{-M}) \cdot 2^e & \text{if } m < 2^M \wedge 2 - 2^{E-1} \leq e \leq 2^{E-1} - 1 \\ (0 + m \cdot 2^{-M}) \cdot 2^e & \text{if } m < 2^M \wedge 2 - 2^{E-1} = e \\ \infty & \\ \text{nan}(m) & \text{if } 1 \leq m < 2^M \end{array} \end{aligned}$$

where $M = \text{signif}(N)$ and $E = \text{expon}(N)$ with

$$\begin{aligned} \text{signif}(32) &= 23 \\ \text{signif}(64) &= 52 \\ \text{expon}(32) &= 8 \\ \text{expon}(64) &= 11 \end{aligned}$$

A *canonical NaN* is a floating-point value $\pm \text{nan}(\text{canon}_N)$ where canon_N is a payload whose most significant bit is 1 while all others are 0:

$$\text{canon}_N = 2^{\text{signif}(N)-1}$$

An *arithmetic NaN* is a floating-point value $\pm \text{nan}(m)$ with $m \geq \text{canon}_N$, such that the most significant bit is 1 while all others are arbitrary.

Note

In the abstract syntax, subnormals are distinguished by the leading 0 of the significand. The exponent of subnormals has the same value as the smallest possible exponent of a normal number. Only in the [binary representation](#) the exponent of a subnormal is encoded differently than the exponent of any normal number.

The notion of canonical NaN defined here is unrelated to the notion of canonical NaN that the [IEEE 754](#)¹⁰ standard (Section 3.5.2) defines for decimal interchange formats.

Conventions

- The meta variable z ranges over floating-point values where clear from context.
- Where clear from context, shorthands like $+1$ denote floating point values like $+(1 + 1 \cdot 2^{-M}) \cdot 2^0$.

2.2.4 Vectors

Numeric vectors are 128-bit values that are processed by vector instructions (also known as *SIMD* instructions, single instruction multiple data). They are represented in the abstract syntax using [u128](#). The interpretation of lane types ([integer](#) or [floating-point](#) numbers) and lane sizes are determined by the specific instruction operating on them.

2.2.5 Names

Names are sequences of *characters*, which are *scalar values* as defined by [Unicode](#)¹¹ (Section 2.4).

$$\begin{aligned} \text{name} &::= \text{char}^* && \text{if } |\text{utf8}(\text{char}^*)| < 2^{32} \\ \text{char} &::= \text{U+00} \mid \dots \mid \text{U+D7FF} \mid \text{U+E000} \mid \dots \mid \text{U+10FFFF} \end{aligned}$$

Due to the limitations of the [binary format](#), the length of a name is bounded by the length of its [UTF-8](#) encoding.

¹⁰ <https://ieeexplore.ieee.org/document/8766229>

¹¹ <https://www.unicode.org/versions/latest/>

Convention

- Characters (Unicode scalar values) are sometimes used interchangeably with natural numbers $n < 1114112$.

2.3 Types

Various entities in WebAssembly are classified by types. Types are checked during [validation](#), [instantiation](#), and possibly [execution](#).

2.3.1 Number Types

Number types classify numeric values.

$$\text{numtype} ::= \text{i32} \mid \text{i64} \mid \text{f32} \mid \text{f64}$$

The types `i32` and `i64` classify 32 and 64 bit integers, respectively. Integers are not inherently signed or unsigned, their interpretation is determined by individual operations.

The types `f32` and `f64` classify 32 and 64 bit floating-point data, respectively. They correspond to the respective binary floating-point representations, also known as *single* and *double* precision, as defined by the [IEEE 754](#)¹² standard (Section 3.3).

Number types are *transparent*, meaning that their bit patterns can be observed. Values of number type can be stored in [memories](#).

Conventions

- The notation $|t|$ denotes the *bit width* of a number type t . That is, $|i32| = |f32| = 32$ and $|i64| = |f64| = 64$.

2.3.2 Vector Types

Vector types classify vectors of [numeric](#) values processed by vector instructions (also known as *SIMD* instructions, single instruction multiple data).

$$\text{vectype} ::= \text{v128}$$

The type `v128` corresponds to a 128 bit vector of packed integer or floating-point data. The packed data can be interpreted as signed or unsigned integers, single or double precision floating-point values, or a single 128 bit type. The interpretation is determined by individual operations.

Vector types, like [number types](#) are *transparent*, meaning that their bit patterns can be observed. Values of vector type can be stored in [memories](#).

Conventions

- The notation $|t|$ for [bit width](#) extends to vector types as well, that is, $|v128| = 128$.

2.3.3 Type Uses

A *type use* is the use site of a [type index](#) referencing a [composite type defined](#) in a [module](#). It classifies objects of the respective type.

$$\text{typeuse} ::= \text{typeid} \mid \dots$$

The syntax of type uses is [extended](#) with additional forms for the purpose of specifying [validation](#) and [execution](#).

¹² <https://ieeexplore.ieee.org/document/8766229>

2.3.4 Heap Types

Heap types classify objects in the runtime store. There are three disjoint hierarchies of heap types:

- *function types* classify *functions*,
- *aggregate types* classify dynamically allocated *managed* data, such as *structures*, *arrays*, or *unboxed scalars*,
- *external types* classify *external* references possibly owned by the *embedder*.

The values from the latter two hierarchies are interconvertible by ways of the `extern.convert_any` and `any.convert_extern` instructions. That is, both type hierarchies are inhabited by an isomorphic set of values, but may have different, incompatible representations in practice.

```

absheaptype ::= any | eq | i31 | struct | array | none
              | func | nofunc
              | exn | noexn
              | extern | noextern
              | ...
heaptype    ::= absheaptype | typeuse

```

A heap type is either *abstract* or *concrete*. A concrete heap type consists of a *type use* that classifies an object of the respective *type* defined in a module. Abstract types are denoted by individual keywords.

The type `func` denotes the common supertype of all *function types*, regardless of their concrete definition. Dually, the type `nofunc` denotes the common subtype of all *function types*, regardless of their concrete definition. This type has no values.

The type `exn` denotes the common supertype of all *exception references*. This type has no concrete subtypes. Dually, the type `noexn` denotes the common subtype of all forms of exception references. This type has no values.

The type `extern` denotes the common supertype of all external references received through the *embedder*. This type has no concrete subtypes. Dually, the type `noextern` denotes the common subtype of all forms of external references. This type has no values.

The type `any` denotes the common supertype of all aggregate types, as well as possibly abstract values produced by *internalizing* an external reference of type `extern`. Dually, the type `none` denotes the common subtype of all forms of aggregate types. This type has no values.

The type `eq` is a subtype of `any` that includes all types for which references can be compared, i.e., aggregate values and `i31`.

The types `struct` and `array` denote the common supertypes of all *structure* and *array* aggregates, respectively.

The type `i31` denotes *unboxed scalars*, that is, integers injected into references. Their observable value range is limited to 31 bits.

Note

Values of type `i31` are not actually allocated in the store, but represented in a way that allows them to be mixed with actual references into the store without ambiguity. Engines need to perform some form of *pointer tagging* to achieve this, which is why one bit is reserved. Since this type is to be reliably unboxed on all hardware platforms supported by WebAssembly, it cannot be wider than 32 bits minus the tag bit.

Although the types `none`, `nofunc`, `noexn`, and `noextern` are not inhabited by any values, they can be used to form the types of all null *references* in their respective hierarchy. For example, `(ref null nofunc)` is the generic type of a null reference compatible with all function reference types.

The syntax of abstract heap types is *extended* with additional forms for the purpose of specifying *validation* and *execution*.

2.3.5 Reference Types

Reference types classify *values* that are first-class references to objects in the runtime *store*.

$$reftype ::= \text{ref null}^? \text{ heaptype}$$

A reference type is characterised by the *heap type* it points to.

In addition, a reference type of the form `ref null ht` is *nullable*, meaning that it can either be a proper reference to *ht* or *null*. Other references are *non-null*.

Reference types are *opaque*, meaning that neither their size nor their bit pattern can be observed. Values of reference type can be stored in *tables* but not in *memories*.

Conventions

- The reference type *anyref* is an abbreviation for `(ref null any)`.
- The reference type *eqref* is an abbreviation for `(ref null eq)`.
- The reference type *i31ref* is an abbreviation for `(ref null i31)`.
- The reference type *structref* is an abbreviation for `(ref null struct)`.
- The reference type *arrayref* is an abbreviation for `(ref null array)`.
- The reference type *funcref* is an abbreviation for `(ref null func)`.
- The reference type *exnref* is an abbreviation for `(ref null exn)`.
- The reference type *externref* is an abbreviation for `(ref null extern)`.
- The reference type *nullref* is an abbreviation for `(ref null none)`.
- The reference type *nullfuncref* is an abbreviation for `(ref null nofunc)`.
- The reference type *nullexnref* is an abbreviation for `(ref null noexn)`.
- The reference type *nullexternref* is an abbreviation for `(ref null noextern)`.

2.3.6 Value Types

Value types classify the individual values that WebAssembly code can compute with and the values that a variable accepts. They are either *number types*, *vector types*, or *reference types*.

$$\begin{aligned} consttype &::= \text{numtype} \mid \text{vectype} \\ valtype &::= \text{numtype} \mid \text{vectype} \mid \text{reftype} \mid \dots \end{aligned}$$

The syntax of value types is *extended* with additional forms for the purpose of specifying *validation*.

Conventions

- The meta variable *t* ranges over value types or subclasses thereof where clear from context.

2.3.7 Result Types

Result types classify the result of *executing instructions* or *functions*, which is a sequence of values, written with brackets.

$$resulttype ::= \text{list}(valtype)$$

2.3.8 Block Types

Block types classify the *input* and *output* of structured *control instructions* delimiting *blocks* of instructions.

$$\begin{aligned} \text{blocktype} &::= \text{valtype}^? \\ &\quad | \text{funcidx} \end{aligned}$$

They are given either as a *type index* that refers to a suitable *function type* reinterpreted as an *instruction type*, or as an optional *value type* inline, which is a shorthand for the instruction type $\epsilon \rightarrow \text{valtype}^?$.

2.3.9 Composite Types

Composite types are all types composed from simpler types, including *function types*, *structure types* and *array types*.

$$\begin{aligned} \text{comptype} &::= \text{struct } \text{list}(\text{fieldtype}) \\ &\quad | \text{array } \text{fieldtype} \\ &\quad | \text{func } \text{resulttype} \rightarrow \text{resulttype} \\ \text{fieldtype} &::= \text{mut}^? \text{ storagetype} \\ \text{storagetype} &::= \text{valtype} \mid \text{packtype} \\ \text{packtype} &::= \text{i8} \mid \text{i16} \end{aligned}$$

Function types classify the signature of *functions*, mapping a list of parameters to a list of results. They are also used to classify the inputs and outputs of *instructions*.

Aggregate types like structure or array types consist of a list of possibly mutable, possibly packed *field types* describing their components. Structures are heterogeneous, but require static indexing, while arrays need to be homogeneous, but allow dynamic indexing.

Conventions

- The notation $|t|$ for the *bit width* of a *value type* t extends to packed types as well, that is, $|\text{i8}| = 8$ and $|\text{i16}| = 16$.
- The auxiliary function *unpack* maps a storage type to the *value type* obtained when accessing a field:

2.3.10 Recursive Types

Recursive types denote a group of mutually recursive *composite types*, each of which can optionally declare a list of *type uses* of supertypes that it *matches*. Each type can also be declared *final*, preventing further subtyping.

$$\begin{aligned} \text{rectype} &::= \text{rec } \text{list}(\text{subtype}) \\ \text{subtype} &::= \text{sub } \text{final}^? \text{ typeuse}^* \text{ comptype} \end{aligned}$$

In a *module*, each member of a recursive type is assigned a separate *type index*.

2.3.11 Address Types

Address types are a subset of *number types* that classify the values that can be used as offsets into *memories* and *tables*.

$$\text{addrtype} ::= \text{i32} \mid \text{i64}$$

Conventions

The *minimum* of two address types is defined as the address type whose *bit width* is the minimum of the two.

$$\begin{aligned} \min(\text{at}_1, \text{at}_2) &= \text{at}_1 \quad \text{if } |\text{at}_1| \leq |\text{at}_2| \\ \min(\text{at}_1, \text{at}_2) &= \text{at}_2 \quad \text{otherwise} \end{aligned}$$

2.3.12 Limits

Limits classify the size range of resizable storage associated with [memory types](#) and [table types](#).

$$limits ::= [u64 .. u64]$$

2.3.13 Tag Types

Tag types classify the signature [tags](#) with a [type use](#) referring to the definition of a [function type](#) that declares the types of parameter and result values associated with the tag. The result type is empty for exception tags.

$$tagtype ::= typeuse$$

2.3.14 Global Types

Global types classify [global](#) variables, which hold a value and can either be mutable or immutable.

$$globaltype ::= mut^? valtype$$

2.3.15 Memory Types

Memory types classify linear [memories](#) and their size range.

$$memtype ::= addrtype limits page$$

The limits constrain the minimum and optionally the maximum size of a memory. The limits are given in units of page size.

2.3.16 Table Types

Table types classify [tables](#) over elements of [reference type](#) within a size range.

$$tabletype ::= addrtype limits reftype$$

Like memories, tables are constrained by limits for their minimum and optionally maximum size. The limits are given in numbers of entries.

2.3.17 Data Types

Data types classify [data segments](#). Since the contents of a data segment requires no further classification, they merely consist of a universal marker `ok` indicating well-formedness.

$$datatype ::= ok$$

2.3.18 Element Types

Element types classify [element segments](#) by the [reference type](#) of its elements.

$$elemtype ::= reftype$$

2.3.19 External Types

External types classify [imports](#) and [external addresses](#) with their respective types.

$$\textit{externtype} ::= \text{tag } \textit{tagtype} \mid \text{global } \textit{globaltype} \mid \text{mem } \textit{memtype} \mid \text{table } \textit{tabletype} \mid \text{func } \textit{typeuse}$$

For functions, the [type use](#) has to refer to the definition of a [function type](#).

Note

Future versions of WebAssembly may have additional uses for tags, and may allow non-empty result types in the function types of tags.

Conventions

The following auxiliary notation is defined for sequences of external types. It filters out entries of a specific kind in an order-preserving fashion:

$\text{funcs}(\epsilon)$	$= \epsilon$	
$\text{funcs}((\text{func } dt) \textit{xt}^*)$	$= dt \text{ funcs}(\textit{xt}^*)$	
$\text{funcs}(\textit{externtype } \textit{xt}^*)$	$= \text{funcs}(\textit{xt}^*)$	otherwise
$\text{tables}(\epsilon)$	$= \epsilon$	
$\text{tables}((\text{table } tt) \textit{xt}^*)$	$= tt \text{ tables}(\textit{xt}^*)$	
$\text{tables}(\textit{externtype } \textit{xt}^*)$	$= \text{tables}(\textit{xt}^*)$	otherwise
$\text{mems}(\epsilon)$	$= \epsilon$	
$\text{mems}((\text{mem } mt) \textit{xt}^*)$	$= mt \text{ mems}(\textit{xt}^*)$	
$\text{mems}(\textit{externtype } \textit{xt}^*)$	$= \text{mems}(\textit{xt}^*)$	otherwise
$\text{globals}(\epsilon)$	$= \epsilon$	
$\text{globals}((\text{global } gt) \textit{xt}^*)$	$= gt \text{ globals}(\textit{xt}^*)$	
$\text{globals}(\textit{externtype } \textit{xt}^*)$	$= \text{globals}(\textit{xt}^*)$	otherwise
$\text{tags}(\epsilon)$	$= \epsilon$	
$\text{tags}((\text{tag } jt) \textit{xt}^*)$	$= jt \text{ tags}(\textit{xt}^*)$	
$\text{tags}(\textit{externtype } \textit{xt}^*)$	$= \text{tags}(\textit{xt}^*)$	otherwise

2.4 Instructions

WebAssembly code consists of sequences of *instructions*. Its computational model is based on a *stack machine* in that instructions manipulate values on an implicit *operand stack*, consuming (popping) argument values and producing or returning (pushing) result values.

In addition to dynamic operands from the stack, some instructions also have static *immediate* arguments, typically [indices](#) or type annotations, which are part of the instruction itself.

Some instructions are [structured](#) in that they contain nested sequences of instructions.

The following sections group instructions into a number of different categories.

The syntax of instruction is further [extended](#) with additional forms for the purpose of specifying [execution](#).

2.4.1 Parametric Instructions

Instructions in this group can operate on operands of any [value type](#).

$$\textit{instr} ::= \begin{array}{l} \text{nop} \\ | \\ \text{unreachable} \\ | \\ \text{drop} \\ | \\ \text{select } (\textit{valtype}^*)^? \\ | \\ \dots \end{array}$$

The nop instruction does nothing.

The unreachable instruction causes an unconditional [trap](#).

The drop instruction simply throws away a single operand.

The select instruction selects one of its first two operands based on whether its third operand is zero or not. It may include a [value type](#) determining the type of these operands. If missing, the operands must be of [numeric](#) or [vector](#) type.

Note

In future versions of WebAssembly, the type annotation on select may allow for more than a single value being selected at the same time.

2.4.2 Control Instructions

Instructions in this group affect the flow of control.

```

instr ::= ...
        | block blocktype instr*
        | loop blocktype instr*
        | if blocktype instr* else instr*
        | br labelidx
        | br_if labelidx
        | br_table labelidx* labelidx
        | br_on_null labelidx
        | br_on_non_null labelidx
        | br_on_cast labelidx reftype reftype
        | br_on_cast_fail labelidx reftype reftype
        | call funcidx
        | call_ref typeuse
        | call_indirect tableidx typeuse
        | return
        | return_call funcidx
        | return_call_ref typeuse
        | return_call_indirect tableidx typeuse
        | throw tagidx
        | throw_ref
        | try_table blocktype list(catch) instr*
        | ...

catch ::= catch tagidx labelidx
        | catch_ref tagidx labelidx
        | catch_all labelidx
        | catch_all_ref labelidx

```

The block, loop, if and try_table instructions are *structured* instructions. They bracket nested sequences of instructions, called *blocks*. As the grammar prescribes, they must be well-nested.

A structured instruction can consume *input* and produce *output* on the operand stack according to its annotated [block type](#).

Each structured control instruction introduces an implicit *label*. Labels are targets for branch instructions that reference them with [label indices](#). Unlike with other [index spaces](#), indexing of labels is relative by nesting depth, that is, label 0 refers to the innermost structured control instruction enclosing the referring branch instruction, while increasing indices refer to those farther out. Consequently, labels can only be referenced from *within* the associated structured control instruction. This also implies that branches can only be directed outwards, “breaking” from the block of the control construct they target. The exact effect depends on that control construct. In case of block or if it is a *forward jump*, resuming execution after the end of the block. In case of loop it is a *backward jump* to the beginning of the loop.

Note

This enforces *structured control flow*. Intuitively, a branch targeting a block or if behaves like a break statement in most C-like languages, while a branch targeting a loop behaves like a continue statement.

Branch instructions come in several flavors: `br` performs an unconditional branch, `br_if` performs a conditional branch, and `br_table` performs an indirect branch through an operand indexing into the label list that is an immediate to the instruction, or to a default target if the operand is out of bounds. The `br_on_null` and `br_on_non_null` instructions check whether a reference operand is `null` and branch if that is the case or not the case, respectively. Similarly, `br_on_cast` and `br_on_cast_fail` attempt a downcast on a reference operand and branch if that succeeds, or fails, respectively.

The `return` instruction is a shortcut for an unconditional branch to the outermost block, which implicitly is the body of the current function. Taking a branch *unwinds* the operand stack up to the height where the targeted structured control instruction was entered. However, branches may additionally consume operands themselves, which they push back on the operand stack after unwinding. Forward branches require operands according to the output of the targeted block's type, i.e., represent the values produced by the terminated block. Backward branches require operands according to the input of the targeted block's type, i.e., represent the values consumed by the restarted block.

The `call` instruction invokes another [function](#), consuming the necessary arguments from the stack and returning the result values of the call. The `call_ref` instruction invokes a function indirectly through a [function reference](#) operand. The `call_indirect` instruction calls a function indirectly through an operand indexing into a [table](#) that is denoted by a [table index](#) and must contain [function references](#). Since it may contain functions of heterogeneous type, the callee is dynamically checked against the [function type](#) indexed by the instruction's second immediate, and the call is aborted with a [trap](#) if it does not match.

The `return_call`, `return_call_ref`, and `return_call_indirect` instructions are *tail-call* variants of the previous ones. That is, they first return from the current function before actually performing the respective call. It is guaranteed that no sequence of nested calls using only these instructions can cause resource exhaustion due to hitting an [implementation's limit](#) on the number of active calls.

The instructions `throw`, `throw_ref`, and `try_table` are concerned with *exceptions*. The `throw` and `throw_ref` instructions raise and reraise an exception, respectively, and transfers control to the innermost enclosing exception handler that has a matching catch clause. The `try_table` instruction installs an exception *handler* that handles exceptions as specified by its catch clauses.

2.4.3 Variable Instructions

Variable instructions are concerned with access to [local](#) or [global](#) variables.

```

instr ::= ...
      | local.get localidx
      | local.set localidx
      | local.tee localidx
      | global.get globalidx
      | global.set globalidx
      | ...

```

These instructions get or set the values of respective variables. The `local.tee` instruction is like `local.set` but also returns its argument.

2.4.4 Table Instructions

Instructions in this group are concerned with tables `table`.

```

instr ::= ...
        | table.get tableidx
        | table.set tableidx
        | table.size tableidx
        | table.grow tableidx
        | table.fill tableidx
        | table.copy tableidx tableidx
        | table.init tableidx elemidx
        | elem.drop elemidx
        | ...

```

The `table.get` and `table.set` instructions load or store an element in a table, respectively.

The `table.size` instruction returns the current size of a table. The `table.grow` instruction grows table by a given delta and returns the previous size, or -1 if enough space cannot be allocated. It also takes an initialization value for the newly allocated entries.

The `table.fill` instruction sets all entries in a range to a given value. The `table.copy` instruction copies elements from a source table region to a possibly overlapping destination region; the first index denotes the destination. The `table.init` instruction copies elements from a [passive element segment](#) into a table.

The `elem.drop` instruction prevents further use of a passive element segment. This instruction is intended to be used as an optimization hint. After an element segment is dropped its elements can no longer be retrieved, so the memory used by this segment may be freed.

Note

An additional instruction that accesses a table is the [control instruction](#) `call_indirect`.

2.4.5 Memory Instructions

Instructions in this group are concerned with linear [memory](#).

```

memarg ::= {align u32, offset u32}
loadopiN ::= sz_sx                                     if sz < N
storeopiN ::= sz                                         if sz < N
vloadopvectype ::= sz × M_sx                           if sz · M = |vectype|/2
                  | sz_splat
                  | sz_zero                               if sz ≥ 32
instr ::= ...
        | numtype.load?loadopnumtype memidx memarg
        | numtype.store?storeopnumtype memidx memarg
        | vectype.load?vloadopvectype memidx memarg
        | vectype.load?sz_lane memidx memarg laneidx
        | vectype.store memidx memarg
        | vectype.store?sz_lane memidx memarg laneidx
        | memory.size memidx
        | memory.grow memidx
        | memory.fill memidx
        | memory.copy memidx memidx
        | memory.init memidx dataidx
        | data.drop dataidx
        | ...

```

Memory is accessed with load and store instructions for the different [number types](#) and *vector types* `<syntax-vec>`. They all take a [memory index](#) and a *memory argument* `memarg` that contains an address *offset* and the expected *alignment* (expressed as the exponent of a power of 2).

Integer loads and stores can optionally specify a *storage size* `sz` that is smaller than the [bit width](#) of the respective value type. In the case of loads, a sign extension mode `sx` is then required to select appropriate behavior.

Vector loads can specify a shape that is half the [bit width](#) of `v128`. Each lane is half its usual size, and the sign extension mode `sx` then specifies how the smaller lane is extended to the larger lane. Alternatively, vector loads can perform a *splat*, such that only a single lane of the specified storage size is loaded, and the result is duplicated to all lanes.

The static address offset is added to the dynamic address operand, yielding a 33-bit or 65-bit *effective address* that is the zero-based index at which the memory is accessed. All values are read and written in [little endian](#)¹³ byte order. A [trap](#) results if any of the accessed memory bytes lies outside the address range implied by the memory's current size.

The `memory.size` instruction returns the current size of a memory. The `memory.grow` instruction grows a memory by a given delta and returns the previous size, or `-1` if enough memory cannot be allocated. Both instructions operate in units of [page size](#).

The `memory.fill` instruction sets all values in a region of a memory to a given byte. The `memory.copy` instruction copies data from a source memory region to a possibly overlapping destination region in another or the same memory; the first index denotes the destination. The `memory.init` instruction copies data from a [passive data segment](#) into a memory.

The `data.drop` instruction prevents further use of a passive data segment. This instruction is intended to be used as an optimization hint. After a data segment is dropped its data can no longer be retrieved, so the memory used by this segment may be freed.

2.4.6 Reference Instructions

Instructions in this group are concerned with accessing [references](#).

```
instr ::= ...
        | ref.func funcidx
        | ref.null heapttype
        | ref.is_null
        | ref.as_non_null
        | ref.eq
        | ref.test reftype
        | ref.cast reftype
        | ...
```

The `ref.null` and `ref.func` instructions produce a [null](#) reference or a reference to a given function, respectively.

The instruction `ref.is_null` checks for null, while `ref.as_non_null` converts a [nullable](#) to a non-null one, and [traps](#) if it encounters null.

The `ref.eq` compares two references.

The instructions `ref.test` and `ref.cast` test the [dynamic type](#) of a reference operand. The former merely returns the result of the test, while the latter performs a downcast and [traps](#) if the operand's type does not match.

Note

The `br_on_null` and `br_on_non_null` instructions provide versions of `ref.as_null` that branch depending on the success or failure of a null test instead of trapping. Similarly, the `br_on_cast` and `br_on_cast_fail` instructions provide versions of `ref.cast` that branch depending on the success of the downcast instead of trapping.

An additional instruction operating on function references is the [control instruction](#) `call_ref`.

¹³ <https://en.wikipedia.org/wiki/Endianness#Little-endian>

2.4.7 Aggregate Instructions

Instructions in this group are concerned with creating and accessing [references](#) to [aggregate](#) types.

```

instr ::= ...
        | struct.new typeidx
        | struct.new_default typeidx
        | struct.get_sx? typeidx u32
        | struct.set typeidx u32
        | array.new typeidx
        | array.new_default typeidx
        | array.new_fixed typeidx u32
        | array.new_data typeidx dataidx
        | array.new_elem typeidx elemidx
        | array.get_sx? typeidx
        | array.set typeidx
        | array.len
        | array.fill typeidx
        | array.copy typeidx typeidx
        | array.init_data typeidx dataidx
        | array.init_elem typeidx elemidx
        | ref.i31
        | i31.get_sx
        | extern.convert_any
        | any.convert_extern
        | ...

```

The instructions `struct.new` and `struct.new_default` allocate a new [structure](#), initializing them either with operands or with default values. The remaining instructions on structs access individual fields, allowing for different sign extension modes in the case of [packed](#) storage types.

Similarly, [arrays](#) can be allocated either with an explicit initialization operand or a default value. Furthermore, `array.new_fixed` allocates an array with statically fixed size, and `array.new_data` and `array.new_elem` allocate an array and initialize it from a [data](#) or [element](#) segment, respectively. The instructions `array.get`, `array.get sx`, and `array.set` access individual slots, again allowing for different sign extension modes in the case of a [packed](#) storage type; `array.len` produces the length of an array; `array.fill` fills a specified slice of an array with a given value and `array.copy`, `array.init_data`, and `array.init_elem` copy elements to a specified slice of an array from a given array, data segment, or element segment, respectively.

The instructions `ref.i31` and `i31.get sx` convert between type `i32` and an unboxed [scalar](#).

The instructions `any.convert_extern` and `extern.convert_any` allow lossless conversion between references represented as type `(ref null extern)` and as `(ref null any)`.

2.4.8 Numeric Instructions

Numeric instructions provide basic operations over numeric *values* of specific *type*. These operations closely match respective operations available in hardware.

<i>sz</i>	::=	8 16 32 64	
<i>sx</i>	::=	u s	
<i>num_{iN}</i>	::=	<i>iN</i>	
<i>num_{fN}</i>	::=	<i>fN</i>	
<i>instr</i>	::=	...	
		<i>numtype.const num_{numtype}</i>	
		<i>numtype.unop_{numtype}</i>	
		<i>numtype.binop_{numtype}</i>	
		<i>numtype.testop_{numtype}</i>	
		<i>numtype.relop_{numtype}</i>	
		<i>numtype₁.cvtop_{numtype₂, numtype₁—numtype₂}</i>	
		...	
<i>unop_{iN}</i>	::=	clz ctz popcnt extend _{sz_s}	if <i>sz</i> < <i>N</i>
<i>unop_{fN}</i>	::=	abs neg sqrt ceil floor trunc nearest	
<i>binop_{iN}</i>	::=	add sub mul div _{sx} rem _{sx}	
		and or xor shl shr _{sx} rotl rotr	
<i>binop_{fN}</i>	::=	add sub mul div min max copysign	
<i>testop_{iN}</i>	::=	eqz	
<i>relop_{iN}</i>	::=	eq ne lt _{sx} gt _{sx} le _{sx} ge _{sx}	
<i>relop_{fN}</i>	::=	eq ne lt gt le ge	
<i>cvtop_{iN₁,iN₂}</i>	::=	extend _{sx}	if <i>N₁</i> < <i>N₂</i>
		wrap	if <i>N₁</i> > <i>N₂</i>
<i>cvtop_{iN₁,fN₂}</i>	::=	convert _{sx}	
		reinterpret	if <i>N₁</i> = <i>N₂</i>
<i>cvtop_{fN₁,iN₂}</i>	::=	trunc _{sx}	
		trunc_sat _{sx}	
		reinterpret	if <i>N₁</i> = <i>N₂</i>
<i>cvtop_{fN₁,fN₂}</i>	::=	promote	if <i>N₁</i> < <i>N₂</i>
		demote	if <i>N₁</i> > <i>N₂</i>

Numeric instructions are divided by *number type*. For each type, several subcategories can be distinguished:

- *Constants*: return a static constant.
- *Unary Operations*: consume one operand and produce one result of the respective type.
- *Binary Operations*: consume two operands and produce one result of the respective type.
- *Tests*: consume one operand of the respective type and produce a Boolean integer result.
- *Comparisons*: consume two operands of the respective type and produce a Boolean integer result.
- *Conversions*: consume a value of one type and produce a result of another (the source type of the conversion is the one after the “_”).

Some integer instructions come in two flavors, where a signedness annotation *sx* distinguishes whether the operands are to be interpreted as *unsigned* or *signed* integers. For the other integer instructions, the use of two’s complement for the signed interpretation means that they behave the same regardless of signedness.

2.4.9 Vector Instructions

Vector instructions (also known as *SIMD* instructions, *single instruction multiple data*) provide basic operations over values of vector type.

<i>lanetype</i>	::=	<i>numtype</i> <i>packtype</i>	
<i>dim</i>	::=	1 2 4 8 16	
<i>shape</i>	::=	<i>lanetype</i> <i>x</i> <i>dim</i>	if $ lanetype \cdot dim = 128$
<i>ishape</i>	::=	<i>shape</i>	if $lanetype(shape) = iN$
<i>bshape</i>	::=	<i>shape</i>	if $lanetype(shape) = i8$
<i>half</i>	::=	low high	
<i>zero</i>	::=	zero	
<i>laneidx</i>	::=	<i>us</i>	
<i>instr</i>	::=	...	
		<i>vectype</i> .const <i>vec</i> _{<i>vectype</i>}	
		<i>vectype</i> .vvunop	
		<i>vectype</i> .vbinop	
		<i>vectype</i> .vternop	
		<i>vectype</i> .vtestop	
		<i>shape</i> .vunop _{<i>shape</i>}	
		<i>shape</i> .vbinop _{<i>shape</i>}	
		<i>shape</i> .vternop _{<i>shape</i>}	
		<i>shape</i> .vtestop _{<i>shape</i>}	
		<i>shape</i> .vrel _{<i>shape</i>}	
		<i>ishape</i> .vshift _{<i>ishape</i>}	
		<i>ishape</i> .bitmask	
		<i>bshape</i> .vswizzlop _{<i>bshape</i>}	
		<i>bshape</i> .shuffle <i>laneidx</i> *	if $ laneidx^* = \dim(bshape)$
		<i>ishape</i> ₁ .vextunop _{<i>ishape</i>₂, <i>ishape</i>₁ - <i>ishape</i>₂}	
		<i>ishape</i> ₁ .vextbinop _{<i>ishape</i>₂, <i>ishape</i>₁ - <i>ishape</i>₂}	
		<i>ishape</i> ₁ .vextternop _{<i>ishape</i>₂, <i>ishape</i>₁ - <i>ishape</i>₂}	
		<i>ishape</i> ₁ .narrow_ <i>ishape</i> ₂ _sx	if $ lanetype(ishape_2) = 2 \cdot lanetype(ishape_1) \leq 32$
		<i>shape</i> ₁ .vcvtop _{<i>shape</i>₂, <i>shape</i>₁ - <i>shape</i>₂}	
		<i>shape</i> .splat	
		<i>shape</i> .extract_lane_ <i>sx</i> ? <i>laneidx</i>	if $sx^? = \epsilon \Leftrightarrow lanetype(shape) \in i32\ i64\ f32\ f64$
		<i>shape</i> .replace_lane <i>laneidx</i>	
		...	

Vector instructions have a naming convention involving a *shape* prefix that determines how their operands will be interpreted, written *txN*, and consisting of a *lane type* *t*, a possibly *packed numeric type*, and its *dimension* *N*, which denotes the number of lanes of that type. Operations are performed point-wise on the values of each lane.

Instructions prefixed with *v128* do not involve a specific interpretation, and treat the *v128* as either an *i128* value or a vector of 128 individual bits.

Note

For example, the shape *i32x4* interprets the operand as four *i32* values, packed into an *i128*. The bit width of the lane type *t* times *N* always is 128.

Vector instructions can be grouped into several subcategories:

- **Constants:** return a static constant.
- **Unary Operations:** consume one v128 operand and produce one v128 result.
- **Binary Operations:** consume two v128 operands and produce one v128 result.
- **Ternary Operations:** consume three v128 operands and produce one v128 result.
- **Tests:** consume one v128 operand and produce a Boolean integer result.
- **Shifts:** consume a v128 operand and an i32 operand, producing one v128 result.

- *Splats*: consume a value of numeric type and produce a v128 result of a specified shape.
- *Extract lanes*: consume a v128 operand and return the numeric value in a given lane.
- *Replace lanes*: consume a v128 operand and a numeric value for a given lane, and produce a v128 result.

Some vector instructions have a signedness annotation *sx* which distinguishes whether the elements in the operands are to be interpreted as *unsigned* or *signed* integers. For the other vector instructions, the use of two's complement for the signed interpretation means that they behave the same regardless of signedness.

Conventions

- The function `lanetype(shape)` extracts the lane type of a shape.
- The function `dim(shape)` extracts the dimension of a shape.
- The function `zeroop(vcvtop)` extracts the zero flag from a vector conversion operator, or returns ϵ if it does not contain any.
- The function `halfop(vcvtop)` extracts the *half* flag from a vector conversion operator, or returns ϵ if it does not contain any.

2.4.10 Expressions

Function bodies, initialization values for *globals*, elements and offsets of *element* segments, and offsets of *data* segments are given as expressions, which are sequences of *instructions*.

$$expr ::= instr^*$$

In some places, validation *restricts* expressions to be *constant*, which limits the set of allowable instructions.

2.5 Modules

WebAssembly programs are organized into *modules*, which are the unit of deployment, loading, and compilation. A module collects definitions for *types*, *tags*, and *globals*, *memories*, *tables*, *functions*. In addition, it can declare *imports* and *exports* and provide initialization in the form of *data* and *element* segments, or a *start function*.

$$module ::= module\ type^* import^* tag^* global^* mem^* table^* func^* data^* elem^* start^? export^*$$

Each of the lists — and thus the entire module — may be empty.

2.5.1 Indices

Definitions are referenced with zero-based *indices*. Each class of definition has its own *index space*, as distinguished by the following classes.

$$\begin{aligned} typeidx &::= idx \\ funcidx &::= idx \\ globalidx &::= idx \\ tableidx &::= idx \\ memidx &::= idx \\ tagidx &::= idx \\ elemidx &::= idx \\ dataidx &::= idx \\ labelidx &::= idx \\ localidx &::= idx \\ fieldidx &::= idx \end{aligned}$$

The index space for *tags*, *globals*, *memories*, *tables*, and *functions* includes respective *imports* declared in the same module. The indices of these imports precede the indices of other definitions in the same index space.

Data indices reference *data segments* and element indices reference *element segments*.

The index space for **locals** is only accessible inside a **function** and includes the parameters of that function, which precede the local variables.

Label indices reference **structured control instructions** inside an instruction sequence.

Each **aggregate type** provides an index space for its **fields**.

Conventions

- The meta variable l ranges over label indices.
- The meta variables x, y range over indices in any of the other index spaces.
- For every index space $abci\mathit{dx}$, the notation $abci\mathit{dx}(A)$ denotes the set of indices from that index space occurring free in A . Sometimes this set is reinterpreted as the **list** of its elements.

Note

For example, if instr^* is `(data.drop 1) (memory.init 2 3)`, then $\mathit{dataidx}_{\mathit{instrs}}(\mathit{instr}^*) = 1\ 3$, or equivalently, the set $\{1, 3\}$.

2.5.2 Types

The **type** section of a module defines a list of **recursive types**, each consisting of a list of **sub types** referenced by individual **type indices**. All **function**, **structure**, or **array** types used in a module must be defined in this section.

$$\mathit{type} ::= \mathit{type} \mathit{rectype}$$

2.5.3 Tags

The **tag** section of a module defines a list of **tags**:

$$\mathit{tag} ::= \mathit{tag} \mathit{tagtype}$$

The **type index** of a tag must refer to a **function type** that declares its **tag type**.

Tags are referenced through **tag indices**, starting with the smallest index not referencing a tag **import**.

2.5.4 Globals

The **global** section of a module defines a list of **global variables** (or **globals** for short):

$$\mathit{global} ::= \mathit{global} \mathit{globaltype} \mathit{expr}$$

Each global stores a single value of the type specified in the **global type**. It also specifies whether a global is immutable or mutable. Moreover, each global is initialized with a value given by a **constant** initializer **expression**.

Globals are referenced through **global indices**, starting with the smallest index not referencing a global **import**.

2.5.5 Memories

The **mem** section of a module defines a list of **linear memories** (or **memories** for short) as described by their memory type:

$$\mathit{mem} ::= \mathit{memory} \mathit{memtype}$$

A memory is a list of raw uninterpreted bytes. The minimum size in the **limits** of its **memory type** specifies the initial size of that memory, while its maximum, if present, restricts the size to which it can grow later. Both are in units of **page size**.

Memories can be initialized through [data segments](#).

Memories are referenced through [memory indices](#), starting with the smallest index not referencing a memory [import](#). Most constructs implicitly reference memory index 0.

2.5.6 Tables

The *table* section of a module defines a list of *tables* described by their *table type*:

$$\text{table} ::= \text{table } \text{tabletype } \text{expr}$$

A table is an array of opaque values of a particular [reference type](#) that is specified by the *table type*. Each table slot is initialized with a value given by a [constant initializer expression](#). Tables can further be initialized through [element segments](#).

The minimum size in the [limits](#) of the table type specifies the initial size of that table, while its maximum restricts the size to which it can grow later.

Tables are referenced through [table indices](#), starting with the smallest index not referencing a table [import](#). Most constructs implicitly reference table index 0.

2.5.7 Functions

The *func* section of a module defines a list of *functions* with the following structure:

$$\begin{aligned} \text{func} &::= \text{func } \text{typeid} \text{ local}^* \text{ expr} \\ \text{local} &::= \text{local } \text{valtype} \end{aligned}$$

The *type index* of a function declares its signature by reference to a [function type](#) defined in the module. The parameters of the function are referenced through 0-based [local indices](#) in the function's body; they are mutable.

The locals declare a list of mutable local variables and their types. These variables are referenced through [local indices](#) in the function's body. The index of the first local is the smallest index not referencing a parameter.

A function's [expression](#) is an [instruction](#) sequence that represents the body of the function. Upon termination it must produce a stack matching the function type's [result type](#).

Functions are referenced through [function indices](#), starting with the smallest index not referencing a function [import](#).

2.5.8 Data Segments

The *data* section of a module defines a list of *data segments*, which can be used to initialize a range of memory from a static [list](#) of [bytes](#).

$$\begin{aligned} \text{data} &::= \text{data } \text{byte}^* \text{ datamode} \\ \text{datamode} &::= \text{active } \text{memidx } \text{expr} \mid \text{passive} \end{aligned}$$

Similar to element segments, data segments have a mode that identifies them as either *active* or *passive*. A passive data segment's contents can be copied into a memory using the `memory.init` instruction. An active data segment copies its contents into a memory during [instantiation](#), as specified by a [memory index](#) and a [constant expression](#) defining an offset into that memory.

Data segments are referenced through [data indices](#).

2.5.9 Element Segments

The *elem* section of a module defines a list of *element segments*, which can be used to initialize a subrange of a table from a static [list](#) of elements.

$$\begin{aligned} \text{elem} &::= \text{elem } \text{reftype } \text{expr}^* \text{ elemmode} \\ \text{elemmode} &::= \text{active } \text{tableidx } \text{expr} \mid \text{passive} \mid \text{declare} \end{aligned}$$

Each element segment defines a [reference type](#) and a corresponding list of [constant element expressions](#).

Element segments have a mode that identifies them as either *active*, *passive*, or *declarative*. A passive element segment's elements can be copied to a table using the `table.init` instruction. An active element segment copies its elements into a table during *instantiation*, as specified by a *table index* and a *constant expression* defining an offset into that table. A declarative element segment is not available at runtime but merely serves to forward-declare references that are formed in code with instructions like `ref.func`. The offset is given by another *constant expression*.

Element segments are referenced through *element indices*.

2.5.10 Start Function

The *start* section of a module declares the *function index* of a *start function* that is automatically invoked when the module is *instantiated*, after *tables* and *memories* have been initialized.

$$\textit{start} ::= \textit{start funcidx}$$

Note

The start function is intended for initializing the state of a module. The module and its exports are not accessible externally before this initialization has completed.

2.5.11 Imports

The *import* section of a module defines a set of *imports* that are required for *instantiation*.

$$\textit{import} ::= \textit{import name name externtype}$$

Each import is labeled by a two-level *name* space, consisting of a *module name* and an *item name* for an entity within that module. Importable definitions are *tags*, *globals*, *memories*, *tables*, and *functions*. Each import is specified by a respective *external type* that a definition provided during instantiation is required to match.

Every import defines an index in the respective *index space*. In each index space, the indices of imports go before the first index of any definition contained in the module itself.

Note

Unlike export names, import names are not necessarily unique. It is possible to import the same module/item name pair multiple times; such imports may even have different type descriptions, including different kinds of entities. A module with such imports can still be instantiated depending on the specifics of how an *embedder* allows resolving and supplying imports. However, embedders are not required to support such overloading, and a WebAssembly module itself cannot implement an overloaded name.

2.5.12 Exports

The *export* section of a module defines a set of *exports* that become accessible to the host environment once the module has been *instantiated*.

$$\begin{aligned} \textit{export} &::= \textit{export name externidx} \\ \textit{externidx} &::= \textit{func funcidx} \mid \textit{global globalidx} \mid \textit{table tableidx} \mid \textit{memory memidx} \mid \textit{tag tagidx} \end{aligned}$$

Each export is labeled by a unique *name*. Exportable definitions are *tags*, *globals*, *memories*, *tables*, and *functions*, which are referenced through a respective index.

Conventions

The following auxiliary notation is defined for sequences of exports, filtering out indices of a specific kind in an order-preserving fashion:

<code>funcs(ϵ)</code>	<code>=</code>	<code>ϵ</code>	
<code>funcs((<code>func</code> x) xx^*)</code>	<code>=</code>	<code>x funcs(xx^*)</code>	
<code>funcs(<i>externidx</i> xx^*)</code>	<code>=</code>	<code>funcs(xx^*)</code>	otherwise
<code>tables(ϵ)</code>	<code>=</code>	<code>ϵ</code>	
<code>tables((<code>table</code> x) xx^*)</code>	<code>=</code>	<code>x tables(xx^*)</code>	
<code>tables(<i>externidx</i> xx^*)</code>	<code>=</code>	<code>tables(xx^*)</code>	otherwise
<code>mems(ϵ)</code>	<code>=</code>	<code>ϵ</code>	
<code>mems((<code>memory</code> x) xx^*)</code>	<code>=</code>	<code>x mems(xx^*)</code>	
<code>mems(<i>externidx</i> xx^*)</code>	<code>=</code>	<code>mems(xx^*)</code>	otherwise
<code>globals(ϵ)</code>	<code>=</code>	<code>ϵ</code>	
<code>globals((<code>global</code> x) xx^*)</code>	<code>=</code>	<code>x globals(xx^*)</code>	
<code>globals(<i>externidx</i> xx^*)</code>	<code>=</code>	<code>globals(xx^*)</code>	otherwise
<code>tags(ϵ)</code>	<code>=</code>	<code>ϵ</code>	
<code>tags((<code>tag</code> x) xx^*)</code>	<code>=</code>	<code>x tags(xx^*)</code>	
<code>tags(<i>externidx</i> xx^*)</code>	<code>=</code>	<code>tags(xx^*)</code>	otherwise

3.1 Conventions

Validation checks that a WebAssembly module is well-formed. Only valid modules can be *instantiated*.

Validity is defined by a *type system* over the *abstract syntax* of a *module* and its contents. For each piece of abstract syntax, there is a typing rule that specifies the constraints that apply to it. All rules are given in two *equivalent* forms:

1. In *prose*, describing the meaning in intuitive form.
2. In *formal notation*, describing the rule in mathematical form.¹⁴

Note

The prose and formal rules are equivalent, so that understanding of the formal notation is *not* required to read this specification. The formalism offers a more concise description in notation that is used widely in programming languages semantics and is readily amenable to mathematical proof.

In both cases, the rules are formulated in a *declarative* manner. That is, they only formulate the constraints, they do not define an algorithm. The skeleton of a sound and complete algorithm for type-checking instruction sequences according to this specification is provided in the *appendix*.

3.1.1 Types

To define the semantics, the definition of some sorts of types is extended to include additional forms. By virtue of not being representable in either the *binary format* or the *text format*, these forms cannot be used in a program; they only occur during *validation* or *execution*.

$$\begin{array}{lll} \text{valtype} & ::= & \dots \mid \text{bot} \\ \text{absheaptypes} & ::= & \dots \mid \text{bot} \\ \text{typeuse} & ::= & \dots \mid \text{deftype} \mid \text{rec.N} \end{array}$$

The unique *value type* *bot* is a *bottom type* that *matches* all value types. Similarly, *bot* is also used as a bottom type of all *heap types*.

¹⁴ The semantics is derived from the following article: Andreas Haas, Andreas Rossberg, Derek Schuff, Ben Titzer, Dan Gohman, Luke Wagner, Alon Zakai, JF Bastien, Michael Holman. *Bringing the Web up to Speed with WebAssembly*¹⁵. Proceedings of the 38th ACM SIGPLAN Conference on Programming Language Design and Implementation (PLDI 2017). ACM 2017.

¹⁵ <https://dl.acm.org/citation.cfm?doid=3062341.3062363>

Note

No validation rule uses bottom types explicitly, but various rules can pick any value or heap type, including bottom. This ensures the existence of [principal types](#), and thus a [validation algorithm](#) without back tracking.

A [type use](#) can consist directly of a [defined type](#). This occurs as the result of [substituting](#) a [type index](#) with its definition.

A type use may also be a *recursive type index*. Such an index refers to the i -th component of a surrounding [recursive type](#). It occurs as the result of [rolling up](#) the definition of a [recursive type](#).

Both extensions affect occurrences of type uses in concrete [heap types](#), in [sub types](#) and in [instructions](#).

A type of any form is *closed* when it does not contain a heap type that is a [type index](#) or a recursive type index without a surrounding [recursive type](#), i.e., all [type indices](#) have been [substituted](#) with their [defined type](#) and all free recursive type indices have been [unrolled](#).

Note

It is an invariant of the semantics that sub types occur only in one of two forms: either as “syntactic” types as in a source module, where all supertypes are type indices, or as “semantic” types, where all supertypes are resolved to either defined types or recursive type indices.

Recursive type indices are local to a recursive type. They are distinguished from regular type indices and represented such that two closed types are syntactically equal if and only if they have the same recursive structure.

Convention

- The *difference* $rt_1 \setminus rt_2$ between two [reference types](#) is defined as follows:

$$\begin{aligned} (\text{ref null}_1^? ht_1) \setminus (\text{ref null } ht_2) &= (\text{ref } ht_1) \\ (\text{ref null}_1^? ht_1) \setminus (\text{ref } ht_2) &= (\text{ref null}_1^? ht_1) \end{aligned}$$

Note

This definition computes an approximation of the reference type that is inhabited by all values from rt_1 except those from rt_2 . Since the type system does not have general union types, the definition only affects the presence of null and cannot express the absence of other values.

3.1.2 Defined Types

Defined types denote the individual types defined in a [module](#). Each such type is represented as a projection from the [recursive type](#) group it originates from, indexed by its position in that group.

$$\text{deftype} ::= \text{rectype}.n$$

Defined types do not occur in the [binary](#) or [text](#) format, but are formed by [rolling up](#) the [recursive types](#) defined in a module.

Note

It is an invariant of the semantics that all [recursive types](#) occurring in defined types are [rolled up](#).

Conventions

- $t[x^* := dt^*]$ denotes the parallel *substitution* of *type indices* x^* with corresponding *defined types* dt^* in type t , provided $|x^*| = |dt^*|$.
- $t[(\text{rec } i)^* := dt^*]$ denotes the parallel substitution of *recursive type indices* $(\text{rec } i)^*$ with *defined types* dt^* in type t , provided $|(\text{rec } i)^*| = |dt^*|$. This substitution does not proceed under *recursive types*, since they are considered local *binders* for all recursive type indices.
- $t[:= dt^*]$ is shorthand for the substitution $t[x^* := dt^*]$, where $x^* = 0 \dots (|dt^*| - 1)$.

Note

All recursive types formed by the semantics are closed with respect to recursive type indices that occur inside them. Hence, substitution of recursive type indices never needs to modify the bodies of recursive types. In addition, all types used for substitution are closed with respect to recursive type indices, such that name capture of recursive type indices cannot occur.

3.1.3 Rolling and Unrolling

In order to allow comparing *recursive types* for *equivalence*, their representation is changed such that all *type indices* internal to the same recursive type are replaced by *recursive type indices*.

Note

This representation is independent of the type index space, so that it is meaningful across module boundaries. Moreover, this representation ensures that types with equivalent recursive structure are also syntactically equal, hence allowing a simple equality check on (closed) types. It gives rise to an *iso-recursive* interpretation of types.

The representation change is performed by two auxiliary operations on the syntax of *recursive types*:

- *Rolling up* a recursive type *substitutes* its internal *type indices* with corresponding *recursive type indices*.
- *Unrolling* a recursive type *substitutes* its *recursive type indices* with the corresponding *defined types*.

These operations are extended to *defined types* and defined as follows:

$$\begin{aligned}
 \text{roll}_x(\text{rectype}) &= \text{rec } (\text{subtype}[(x + i)^{i < n} := (\text{rec}.i)^{i < n}])^n && \text{if } \text{rectype} = \text{rec subtype}^n \\
 \text{unroll}(\text{rectype}) &= \text{rec } (\text{subtype}[(\text{rec}.i)^{i < n} := (\text{rectype}.i)^{i < n}])^n && \text{if } \text{rectype} = \text{rec subtype}^n \\
 \text{roll}_x^*(\text{rectype}) &= ((\text{rec subtype}^n).i)^{i < n} && \text{if } \text{roll}_x(\text{rectype}) = \text{rec subtype}^n \\
 \text{unroll}(\text{rectype}.i) &= \text{subtype}^*[i] && \text{if } \text{unroll}(\text{rectype}) = \text{rec subtype}^*
 \end{aligned}$$

In addition, the following auxiliary relation denotes the *expansion* of a *defined type* or *type use*:

$$\begin{aligned}
 \text{deftype} &\approx \text{comptype} && \text{if } \text{expand}(\text{deftype}) = \text{comptype} \\
 \text{deftype} &\approx_C \text{comptype} && \text{if } \text{deftype} \approx \text{comptype} \\
 \text{typeid}_x &\approx_C \text{comptype} && \text{if } C.\text{types}[\text{typeid}_x] \approx \text{comptype}
 \end{aligned}$$

3.1.4 Instruction Types

Instruction types classify the behaviour of *instructions* or instruction sequences, by describing how they manipulate the *operand stack* and the initialization status of *locals*:

$$\text{instrtype} ::= \text{resulttype} \rightarrow_{\text{localidx}^*} \text{resulttype}$$

An instruction type $t_1^* \rightarrow_{x^*} t_2^*$ describes the required input stack with argument values of types t_1^* that an instruction pops off and the provided output stack with result values of types t_2^* that it pushes back. Moreover, it enumerates the *indices* x^* of locals that have been set by the instruction or sequence.

Note

Instruction types are only used for [validation](#), they do not occur in programs.

3.1.5 Local Types

Local types classify [locals](#), by describing their [value type](#) as well as their *initialization status*:

$$\begin{array}{lcl} \textit{localtype} & ::= & \textit{init} \textit{ valtype} \\ \textit{init} & ::= & \textit{set} \mid \textit{unset} \end{array}$$
Note

Local types are only used for [validation](#), they do not occur in programs.

3.1.6 Contexts

Validity of an individual definition is specified relative to a *context*, which collects relevant information about the surrounding [module](#) and the definitions in scope:

- *Types*: the list of [types](#) defined in the current module.
- *Recursive Types*: the list of [sub types](#) in the current group of recursive types.
- *Functions*: the list of [functions](#) declared in the current module, represented by a [defined type](#) that [expands](#) to their [function type](#).
- *Tables*: the list of [tables](#) declared in the current module, represented by their [table type](#).
- *Memories*: the list of [memories](#) declared in the current module, represented by their [memory type](#).
- *Globals*: the list of [globals](#) declared in the current module, represented by their [global type](#).
- *Tags*: the list of tags declared in the current module, represented by their [tag type](#).
- *Element Segments*: the list of [element segments](#) declared in the current module, represented by the elements' [reference type](#).
- *Data Segments*: the list of [data segments](#) declared in the current module, each represented by an [ok](#) entry.
- *Locals*: the list of [locals](#) declared in the current [function](#) (including parameters), represented by their [local type](#).
- *Labels*: the stack of [labels](#) accessible from the current position, represented by their [result type](#).
- *Return*: the return type of the current [function](#), represented as an optional [result type](#) that is absent when no return is allowed, as in free-standing expressions.
- *References*: the list of [function indices](#) that occur in the module outside functions and can hence be used to form references inside them.

In other words, a context contains a sequence of suitable [types](#) for each [index space](#), describing each defined entry in that space. Locals, labels and return type are only used for validating [instructions](#) in [function bodies](#), and are left empty elsewhere. The label stack is the only part of the context that changes as validation of an instruction sequence proceeds.

More concretely, contexts are defined as [records](#) C with abstract syntax:

$$\text{context} ::= \{ \begin{array}{l} \text{types } \text{deftype}^* \\ \text{recs } \text{subtype}^* \\ \text{tags } \text{tagtype}^* \\ \text{globals } \text{globaltype}^* \\ \text{mems } \text{memtype}^* \\ \text{tables } \text{tabletype}^* \\ \text{funcs } \text{deftype}^* \\ \text{datas } \text{datatype}^* \\ \text{elems } \text{elemtype}^* \\ \text{locals } \text{localtype}^* \\ \text{labels } \text{resulttype}^* \\ \text{return } \text{resulttype}^? \\ \text{refs } \text{funcidx}^* \end{array} \}$$

Convention

A type of any shape can be *closed* to bring it into [closed](#) form relative to a [context](#) it is [valid](#) in, by [substituting](#) each [type index](#) x occurring in it with its own corresponding [defined type](#) $C.\text{types}[x]$, after first closing the types in $C.\text{types}$ themselves.

$$\begin{aligned} \text{clos}_C(t) &= t[:= dt^*] && \text{if } dt^* = \text{clos}^*(C.\text{types}) \\ \text{clos}^*(\epsilon) &= \epsilon \\ \text{clos}^*(dt^* dt_n) &= dt'^* dt_n[:= dt'^*] && \text{if } dt'^* = \text{clos}^*(dt^*) \end{aligned}$$

Note

Free type indices referring to types within the same [recursive type](#) are handled separately by [rolling up](#) recursive types before closing them.

3.1.7 Prose Notation

Validation is specified by stylised rules for each relevant part of the [abstract syntax](#). The rules not only state constraints defining when a phrase is valid, they also classify it with a type. The following conventions are adopted in stating these rules.

- A phrase A is said to be “valid with type T ” if and only if all constraints expressed by the respective rules are met. The form of T depends on the syntactic class of A .

Note

For example, if A is a [function](#), then T is a [defined function type](#); for an A that is a [global](#), T is a [global type](#); and so on.

- The rules implicitly assume a given [context](#) C .
- In some places, this context is locally extended to a context C' with additional entries. The formulation “Under context C' , ... *statement* ...” is adopted to express that the following statement must apply under the assumptions embodied in the extended context.

3.1.8 Formal Notation

Note

This section gives a brief explanation of the notation for specifying typing rules formally. For the interested reader, a more thorough introduction can be found in respective text books.¹⁶

The proposition that a phrase A has a respective type T is written $A : T$. In general, however, typing is dependent on a context C . To express this explicitly, the complete form is a *judgement* $C \vdash A : T$, which says that $A : T$ holds under the assumptions encoded in C .

The formal typing rules use a standard approach for specifying type systems, rendering them into *deduction rules*. Every rule has the following general form:

$$\frac{\text{premise}_1 \quad \text{premise}_2 \quad \dots \quad \text{premise}_n}{\text{conclusion}}$$

Such a rule is read as a big implication: if all premises hold, then the conclusion holds. Some rules have no premises; they are *axioms* whose conclusion holds unconditionally. The conclusion always is a judgment $C \vdash A : T$, and there usually is one respective rule for each relevant construct A of the abstract syntax.

Note

For example, the typing rule for the `i32.add` instruction can be given as an axiom:

$$\overline{C \vdash \text{i32.add} : \text{i32 i32} \rightarrow \text{i32}}$$

The instruction is always valid with type $\text{i32 i32} \rightarrow \text{i32}$ (saying that it consumes two `i32` values and produces one), independent of any side conditions.

An instruction like `global.get` can be typed as follows:

$$\frac{C.\text{globals}[x] = \text{mut } t}{C \vdash \text{global.get } x : \epsilon \rightarrow t}$$

Here, the premise enforces that the immediate `global index` x exists in the context. The instruction produces a value of its respective type t (and does not consume any values). If $C.\text{globals}[x]$ does not exist then the premise does not hold, and the instruction is ill-typed.

Finally, a `structured` instruction requires a recursive rule, where the premise is itself a typing judgement:

$$\frac{C \vdash \text{blocktype} : t_1^* \rightarrow t_2^* \quad \{\text{labels } (t_2^*)\} \oplus C \vdash \text{instr}^* : t_1^* \rightarrow t_2^*}{C \vdash \text{block } \text{blocktype } \text{instr}^* : t_1^* \rightarrow t_2^*}$$

A block instruction is only valid when the instruction sequence in its body is. Moreover, the result type must match the block's annotation `blocktype`. If so, then the block instruction has the same type as the body. Inside the body an additional label of the corresponding result type is available, which is expressed by extending the context C with the additional label information for the premise.

3.2 Types

Simple `types`, such as `number types` are universally valid. However, restrictions apply to most other types, such as `reference types`, `function types`, as well as the limits of `table types` and `memory types`, which must be checked during validation.

Moreover, `block types` are converted to `instruction types` for ease of processing.

¹⁶ For example: Benjamin Pierce. *Types and Programming Languages*¹⁷. The MIT Press 2002

¹⁷ <https://www.cis.upenn.edu/~bcpierce/tapl/>

3.2.1 Number Types

The number type *numtype* is always valid.

$$\overline{C \vdash \text{numtype} : \text{ok}}$$

3.2.2 Vector Types

The vector type *vectype* is always valid.

$$\overline{C \vdash \text{vectype} : \text{ok}}$$

3.2.3 Type Uses

The type use *typeid_x* is valid if:

- The type $C.\text{types}[\text{typeid}_x]$ exists.

$$\frac{C.\text{types}[\text{typeid}_x] = dt}{C \vdash \text{typeid}_x : \text{ok}}$$

3.2.4 Heap Types

The heap type *absheapttype* is always valid.

$$\overline{C \vdash \text{absheapttype} : \text{ok}}$$

3.2.5 Reference Types

The reference type (*ref null[?] heapttype*) is valid if:

- The heap type *heapttype* is valid.

$$\frac{C \vdash \text{heapttype} : \text{ok}}{C \vdash \text{ref null}^? \text{heapttype} : \text{ok}}$$

3.2.6 Value Types

The value type *valtype* is valid if:

- Either:
 - The value type *valtype* is of the form *numtype*.
 - The number type *numtype* is valid.
- Or:
 - The value type *valtype* is of the form *vectype*.
 - The vector type *vectype* is valid.
- Or:
 - The value type *valtype* is of the form *reftype*.
 - The reference type *reftype* is valid.
- Or:
 - The value type *valtype* is of the form *bot*.

3.2.7 Result Types

The result type t^* is valid if:

- For all t in t^* :
 - The value type t is valid.

$$\frac{(C \vdash t : \text{ok})^*}{C \vdash t^* : \text{ok}}$$

3.2.8 Block Types

Block types may be expressed in one of two forms, both of which are converted to instruction types by the following rules.

The block type $typeid x$ is valid as the instruction type $t_1^* \rightarrow t_2^*$ if:

- The type $C.\text{types}[typeid x]$ exists.
- The expansion of $C.\text{types}[typeid x]$ is $(\text{func } t_1^* \rightarrow t_2^*)$.

$$\frac{C.\text{types}[typeid x] \approx \text{func } t_1^* \rightarrow t_2^*}{C \vdash typeid x : t_1^* \rightarrow t_2^*}$$

The block type $valtype^?$ is valid as the instruction type $\epsilon \rightarrow valtype^?$ if:

- If $valtype$ is defined, then:
 - The value type $valtype$ is valid.

$$\frac{(C \vdash valtype : \text{ok})^?}{C \vdash valtype^? : \epsilon \rightarrow valtype^?}$$

3.2.9 Instruction Types

The instruction type $t_1^* \rightarrow_{x^*} t_2^*$ is valid if:

- The result type t_1^* is valid.
- The result type t_2^* is valid.
- For all x in x^* :
 - The local $C.\text{locals}[x]$ exists.

$$\frac{C \vdash t_1^* : \text{ok} \quad C \vdash t_2^* : \text{ok} \quad (C.\text{locals}[x] = lt)^*}{C \vdash t_1^* \rightarrow_{x^*} t_2^* : \text{ok}}$$

3.2.10 Composite Types

The composite type (struct $fieldtype^*$) is valid if:

- For all $fieldtype$ in $fieldtype^*$:
 - The field type $fieldtype$ is valid.

$$\frac{(C \vdash fieldtype : \text{ok})^*}{C \vdash \text{struct } fieldtype^* : \text{ok}}$$

The composite type (array $fieldtype$) is valid if:

- The field type $fieldtype$ is valid.

$$\frac{C \vdash fieldtype : \text{ok}}{C \vdash \text{array } fieldtype : \text{ok}}$$

The composite type (func $t_1^* \rightarrow t_2^*$) is valid if:

- The result type t_1^* is valid.
- The result type t_2^* is valid.

$$\frac{C \vdash t_1^* : \text{ok} \quad C \vdash t_2^* : \text{ok}}{C \vdash \text{func } t_1^* \rightarrow t_2^* : \text{ok}}$$

The field type ($\text{mut}^?$ *storage**type*) is valid if:

- The storage type *storage**type* is valid.

$$\frac{C \vdash \text{storage} : \text{ok}}{C \vdash \text{mut}^? \text{storage} : \text{ok}}$$

The packed type *pack**type* is always valid.

$$\overline{C \vdash \text{pack} : \text{ok}}$$

3.2.11 Recursive Types

Recursive types are validated with respect to the first type index defined by the recursive group.

rec subtype^{*}

The recursive type (*rec subtype*^{*}) is valid for the type index x if:

- Either:
 - The sub type sequence *subtype*^{*} is empty.
- Or:
 - The sub type sequence *subtype*^{*} is of the form *subtype*₁ *subtype*[']^{*}.
 - The sub type *subtype*₁ is valid for the type index x .
 - The recursive type (*rec subtype*[']^{*}) is valid for the type index $x + 1$.

$$\frac{}{C \vdash \text{rec } \epsilon : \text{ok}(x)} \quad \frac{C \vdash \text{subtype}_1 : \text{ok}(x) \quad C \vdash \text{rec } \text{subtype}'^* : \text{ok}(x+1)}{C \vdash \text{rec } (\text{subtype}_1 \text{ subtype}')^* : \text{ok}(x)}$$

sub final[?] y^* *com**type*

The sub type (*sub final*[?] x^* *com**type*) is valid for the type index x_0 if:

- The length of x^* is less than or equal to 1.
- For all x in x^* :
 - The index x is less than x_0 .
 - The type $C.\text{types}[x]$ exists.
 - The sub type $\text{unroll}(C.\text{types}[x])$ is of the form (*sub* x'^* *com**type*[']).
- *com**type*[']^{*} is the concatenation of all such *com**type*['].
- The composite type *com**type* is valid.
- For all *com**type*['] in *com**type*[']^{*}:
 - The composite type *com**type* matches the composite type *com**type*['].

$$\frac{\begin{array}{l} |x^*| \leq 1 \quad (x < x_0)^* \quad (\text{unroll}(C.\text{types}[x]) = \text{sub } x'^* \text{ comtype}')^* \\ C \vdash \text{comtype} : \text{ok} \quad (C \vdash \text{comtype}' \leq \text{comtype}')^* \end{array}}{C \vdash \text{sub final}^? x^* \text{ comtype} : \text{ok}(x_0)}$$

Note

The side condition on the index ensures that a declared supertype is a previously defined types, preventing cyclic subtype hierarchies.

Future versions of WebAssembly may allow more than one supertype.

3.2.12 Limits

Limits must have meaningful bounds that are within a given range.

The limits range $[n .. m]$ is valid within k if:

- n is less than or equal to m .
- m is less than or equal to k .

$$\frac{n \leq m \leq k}{C \vdash [n .. m] : k}$$

3.2.13 Tag Types

The tag type *typeuse* is valid if:

- The type use *typeuse* is valid.
- The expansion of C is $(\text{func } t_1^* \rightarrow t_2^*)$.

$$\frac{C \vdash \text{typeuse} : \text{ok} \quad \text{typeuse} \approx_C \text{func } t_1^* \rightarrow t_2^*}{C \vdash \text{typeuse} : \text{ok}}$$

3.2.14 Global Types

The global type $(\text{mut}^? t)$ is valid if:

- The value type t is valid.

$$\frac{C \vdash t : \text{ok}}{C \vdash \text{mut}^? t : \text{ok}}$$

3.2.15 Memory Types

The memory type $(\text{addrtype } \text{limits } \text{page})$ is valid if:

- The limits range *limits* is valid within 2^{16} .

$$\frac{C \vdash \text{limits} : 2^{16}}{C \vdash \text{addrtype } \text{limits } \text{page} : \text{ok}}$$

3.2.16 Table Types

The table type $(\text{addrtype } \text{limits } \text{reftype})$ is valid if:

- The limits range *limits* is valid within $2^{32} - 1$.
- The reference type *reftype* is valid.

$$\frac{C \vdash \text{limits} : 2^{32} - 1 \quad C \vdash \text{reftype} : \text{ok}}{C \vdash \text{addrtype } \text{limits } \text{reftype} : \text{ok}}$$

3.2.17 External Types

The external type (tag *tagtype*) is valid if:

- The tag type *tagtype* is valid.

$$\frac{C \vdash \text{tagtype} : \text{ok}}{C \vdash \text{tag } \text{tagtype} : \text{ok}}$$

The external type (global *globaltype*) is valid if:

- The global type *globaltype* is valid.

$$\frac{C \vdash \text{globaltype} : \text{ok}}{C \vdash \text{global } \text{globaltype} : \text{ok}}$$

The external type (mem *memtype*) is valid if:

- The memory type *memtype* is valid.

$$\frac{C \vdash \text{memtype} : \text{ok}}{C \vdash \text{mem } \text{memtype} : \text{ok}}$$

The external type (table *tabletype*) is valid if:

- The table type *tabletype* is valid.

$$\frac{C \vdash \text{tabletype} : \text{ok}}{C \vdash \text{table } \text{tabletype} : \text{ok}}$$

The external type (func *typeuse*) is valid if:

- The type use *typeuse* is valid.
- The expansion of C is $(\text{func } t_1^* \rightarrow t_2^*)$.

$$\frac{C \vdash \text{typeuse} : \text{ok} \quad \text{typeuse} \approx_C \text{func } t_1^* \rightarrow t_2^*}{C \vdash \text{func } \text{typeuse} : \text{ok}}$$

3.3 Matching

On most types, a notion of *subtyping* is defined that is applicable in [validation](#) rules, during [module instantiation](#) when checking the types of imports, or during [execution](#), when performing casts.

3.3.1 Number Types

The number type *numtype* matches only itself.

$$\overline{C \vdash \text{numtype} \leq \text{numtype}}$$

3.3.2 Vector Types

The vector type *vectype* matches only itself.

$$\overline{C \vdash \text{vectype} \leq \text{vectype}}$$

3.3.3 Heap Types

The heap type $heapttype_1$ matches the heap type $heapttype_2$ if:

- Either:
 - The heap type $heapttype_2$ is of the form $heapttype_1$.
- Or:
 - The heap type $heapttype'$ is valid.
 - The heap type $heapttype_1$ matches the heap type $heapttype'$.
 - The heap type $heapttype'$ matches the heap type $heapttype_2$.
- Or:
 - The heap type $heapttype_1$ is of the form `eq`.
 - The heap type $heapttype_2$ is of the form `any`.
- Or:
 - The heap type $heapttype_1$ is of the form `i31`.
 - The heap type $heapttype_2$ is of the form `eq`.
- Or:
 - The heap type $heapttype_1$ is of the form `struct`.
 - The heap type $heapttype_2$ is of the form `eq`.
- Or:
 - The heap type $heapttype_1$ is of the form `array`.
 - The heap type $heapttype_2$ is of the form `eq`.
- Or:
 - The heap type $heapttype_1$ is of the form `deftype`.
 - The heap type $heapttype_2$ is of the form `struct`.
 - The expansion of `deftype` is `(struct fieldtype*)`.
- Or:
 - The heap type $heapttype_1$ is of the form `deftype`.
 - The heap type $heapttype_2$ is of the form `array`.
 - The expansion of `deftype` is `(array fieldtype)`.
- Or:
 - The heap type $heapttype_1$ is of the form `deftype`.
 - The heap type $heapttype_2$ is of the form `func`.
 - The expansion of `deftype` is `(func $t_1^* \rightarrow t_2^*$)`.
- Or:
 - The heap type $heapttype_1$ is of the form $deftype_1$.
 - The heap type $heapttype_2$ is of the form $deftype_2$.
 - The defined type $deftype_1$ matches the defined type $deftype_2$.
- Or:
 - The heap type $heapttype_1$ is of the form `typeid x` .
 - The type $C.types[typeidx]$ exists.

- The type $C.\text{types}[typeidx]$ matches the heap type $heaptype_2$.
- Or:
 - The heap type $heaptype_2$ is of the form $typeidx$.
 - The type $C.\text{types}[typeidx]$ exists.
 - The heap type $heaptype_1$ matches the type $C.\text{types}[typeidx]$.
- Or:
 - The heap type $heaptype_1$ is of the form $(rec.i)$.
 - The length of $typeuse^*$ is greater than j .
 - The heap type $heaptype_2$ is of the form $typeuse^*[j]$.
 - The recursive type $C.\text{recs}[i]$ exists.
 - The recursive type $C.\text{recs}[i]$ is of the form $(\text{sub final}^? typeuse^* ct)$.
- Or:
 - The heap type $heaptype_1$ is of the form $none$.
 - The heap type $heaptype_2$ matches the heap type any .
- Or:
 - The heap type $heaptype_1$ is of the form $nofunc$.
 - The heap type $heaptype_2$ matches the heap type $func$.
- Or:
 - The heap type $heaptype_1$ is of the form $noexn$.
 - The heap type $heaptype_2$ matches the heap type exn .
- Or:
 - The heap type $heaptype_1$ is of the form $noextern$.
 - The heap type $heaptype_2$ matches the heap type $extern$.
- Or:
 - The heap type $heaptype_1$ is of the form bot .

$$\begin{array}{c}
 \frac{}{C \vdash heaptype \leq heaptype} \quad \frac{C \vdash heaptype' : ok \quad C \vdash heaptype_1 \leq heaptype' \quad C \vdash heaptype' \leq heaptype_2}{C \vdash heaptype_1 \leq heaptype_2} \\
 \\
 \frac{\overline{C \vdash eq \leq any} \quad \overline{C \vdash i31 \leq eq} \quad \overline{C \vdash struct \leq eq} \quad \overline{C \vdash array \leq eq}}{\frac{\frac{deftype \approx struct \ fieldtype^*}{C \vdash deftype \leq struct} \quad \frac{deftype \approx array \ fieldtype}{C \vdash deftype \leq array} \quad \frac{deftype \approx func \ t_1^* \rightarrow t_2^*}{C \vdash deftype \leq func}} \\
 \frac{C \vdash C.\text{types}[typeidx] \leq heaptype}{C \vdash typeidx \leq heaptype} \quad \frac{C \vdash heaptype \leq C.\text{types}[typeidx]}{C \vdash heaptype \leq typeidx} \\
 \frac{C.\text{recs}[i] = \text{sub final}^? typeuse^* ct}{C \vdash rec.i \leq typeuse^*[j]} \\
 \frac{C \vdash heaptype \leq any}{C \vdash none \leq heaptype} \quad \frac{C \vdash heaptype \leq func}{C \vdash nofunc \leq heaptype} \quad \frac{C \vdash heaptype \leq exn}{C \vdash noexn \leq heaptype} \quad \frac{C \vdash heaptype \leq extern}{C \vdash noextern \leq heaptype} \\
 \frac{}{C \vdash bot \leq heaptype}
 \end{array}$$

3.3.4 Reference Types

The reference type $(\text{ref null}_1^? ht_1)$ matches the reference type $(\text{ref null}_2^? ht_2)$ if:

- The heap type ht_1 matches the heap type ht_2 .
- Either:
 - $\text{null}_1^?$ is absent.
 - $\text{null}_2^?$ is absent.
- Or:
 - $\text{null}_1^?$ is of the form $\text{null}^?$.
 - $\text{null}_2^?$ is of the form null .

$$\frac{C \vdash ht_1 \leq ht_2}{C \vdash \text{ref } ht_1 \leq \text{ref } ht_2} \quad \frac{C \vdash ht_1 \leq ht_2}{C \vdash \text{ref null}^? ht_1 \leq \text{ref null } ht_2}$$

3.3.5 Value Types

The value type $valtype_1$ matches the value type $valtype_2$ if:

- Either:
 - The value type $valtype_1$ is of the form $numtype_1$.
 - The value type $valtype_2$ is of the form $numtype_2$.
 - The number type $numtype_1$ matches the number type $numtype_2$.
- Or:
 - The value type $valtype_1$ is of the form $vectype_1$.
 - The value type $valtype_2$ is of the form $vectype_2$.
 - The vector type $vectype_1$ matches the vector type $vectype_2$.
- Or:
 - The value type $valtype_1$ is of the form $reftype_1$.
 - The value type $valtype_2$ is of the form $reftype_2$.
 - The reference type $reftype_1$ matches the reference type $reftype_2$.
- Or:
 - The value type $valtype_1$ is of the form bot .

$$\overline{C \vdash \text{bot} \leq valtype}$$

3.3.6 Result Types

Subtyping is lifted to result types in a pointwise manner.

The result type t_1^* matches the result type t_2^* if:

- For all t_1 in t_1^* , and corresponding t_2 in t_2^* :
 - The value type t_1 matches the value type t_2 .

$$\frac{(C \vdash t_1 \leq t_2)^*}{C \vdash t_1^* \leq t_2^*}$$

3.3.7 Instruction Types

Subtyping is further lifted to instruction types.

The instruction type $t_{11}^* \rightarrow_{x_1^*} t_{12}^*$ matches the instruction type $t_{21}^* \rightarrow_{x_2^*} t_{22}^*$ if:

- The result type t_{21}^* matches the result type t_{11}^* .
- The result type t_{12}^* matches the result type t_{22}^* .
- The local index sequence x^* is of the form $x_2^* \setminus x_1^*$.
- For all x in x^* :
 - The local $C.\text{locals}[x]$ exists.
 - The local $C.\text{locals}[x]$ is of the form $(\text{set } t)$.

$$\frac{C \vdash t_{21}^* \leq t_{11}^* \quad C \vdash t_{12}^* \leq t_{22}^* \quad x^* = x_2^* \setminus x_1^* \quad (C.\text{locals}[x] = \text{set } t)^*}{C \vdash t_{11}^* \rightarrow_{x_1^*} t_{12}^* \leq t_{21}^* \rightarrow_{x_2^*} t_{22}^*}$$

Note

Instruction types are contravariant in their input and covariant in their output. Moreover, the supertype may ignore variables from the init set x_1^* . It may also *add* variables to the init set, provided these are already set in the context, i.e., are vacuously initialized.

3.3.8 Composite Types

The composite type comptype_1 matches the composite type comptype_2 if:

- Either:
 - The composite type comptype_1 is of the form $(\text{struct } ft_1^* ft_1'^*)$.
 - The composite type comptype_2 is of the form $(\text{struct } ft_2^*)$.
 - For all ft_1 in ft_1^* , and corresponding ft_2 in ft_2^* :
 - * The field type ft_1 matches the field type ft_2 .
- Or:
 - The composite type comptype_1 is of the form $(\text{array } ft_1)$.
 - The composite type comptype_2 is of the form $(\text{array } ft_2)$.
 - The field type ft_1 matches the field type ft_2 .
- Or:
 - The composite type comptype_1 is of the form $(\text{func } t_{11}^* \rightarrow t_{12}^*)$.
 - The composite type comptype_2 is of the form $(\text{func } t_{21}^* \rightarrow t_{22}^*)$.
 - The result type t_{21}^* matches the result type t_{11}^* .
 - The result type t_{12}^* matches the result type t_{22}^* .

$$\frac{(C \vdash ft_1 \leq ft_2)^*}{C \vdash \text{struct } (ft_1^* ft_1'^*) \leq \text{struct } ft_2^*} \quad \frac{C \vdash ft_1 \leq ft_2}{C \vdash \text{array } ft_1 \leq \text{array } ft_2} \quad \frac{C \vdash t_{21}^* \leq t_{11}^* \quad C \vdash t_{12}^* \leq t_{22}^*}{C \vdash \text{func } t_{11}^* \rightarrow t_{12}^* \leq \text{func } t_{21}^* \rightarrow t_{22}^*}$$

3.3.9 Field Types

The field type $(\text{mut}_1^? \text{zt}_1)$ matches the field type $(\text{mut}_2^? \text{zt}_2)$ if:

- The storage type zt_1 matches the storage type zt_2 .
- Either:
 - $\text{mut}_1^?$ is absent.
 - $\text{mut}_2^?$ is absent.
- Or:
 - $\text{mut}_1^?$ is of the form mut .
 - $\text{mut}_2^?$ is of the form mut .
 - The storage type zt_2 matches the storage type zt_1 .

$$\frac{C \vdash \text{zt}_1 \leq \text{zt}_2}{C \vdash \text{zt}_1 \leq \text{zt}_2} \quad \frac{C \vdash \text{zt}_1 \leq \text{zt}_2 \quad C \vdash \text{zt}_2 \leq \text{zt}_1}{C \vdash \text{mut } \text{zt}_1 \leq \text{mut } \text{zt}_2}$$

The storage type storagetype_1 matches the storage type storagetype_2 if:

- Either:
 - The storage type storagetype_1 is of the form valtype_1 .
 - The storage type storagetype_2 is of the form valtype_2 .
 - The value type valtype_1 matches the value type valtype_2 .
- Or:
 - The storage type storagetype_1 is of the form packtype_1 .
 - The storage type storagetype_2 is of the form packtype_2 .
 - The packed type packtype_1 matches the packed type packtype_2 .

The packed type packtype matches only itself.

$$\overline{C \vdash \text{packtype} \leq \text{packtype}}$$

3.3.10 Defined Types

The defined type deftype_1 matches the defined type deftype_2 if:

- Either:
 - The defined type $\text{clos}_C(\text{deftype}_1)$ is of the form $\text{clos}_C(\text{deftype}_2)$.
- Or:
 - The sub type $\text{unroll}(\text{deftype}_1)$ is of the form $(\text{sub final}^? \text{typeuse}^* \text{ct})$.
 - The length of typeuse^* is greater than i .
 - The type use $\text{typeuse}^*[i]$ matches the heap type deftype_2 .

$$\frac{\text{clos}_C(\text{deftype}_1) = \text{clos}_C(\text{deftype}_2)}{C \vdash \text{deftype}_1 \leq \text{deftype}_2}$$

$$\frac{\text{unroll}(\text{deftype}_1) = \text{sub final}^? \text{typeuse}^* \text{ct} \quad C \vdash \text{typeuse}^*[i] \leq \text{deftype}_2}{C \vdash \text{deftype}_1 \leq \text{deftype}_2}$$

Note

Note that there is no explicit definition of type *equivalence*, since it coincides with syntactic equality, as used in the premise of the former rule above.

3.3.11 Limits

The **limits range** $[n_1 .. m_1]$ matches the **limits range** $[n_2 .. m_2]$ if:

- n_1 is greater than or equal to n_2 .
- m_1 is less than or equal to m_2 .

$$\frac{n_1 \geq n_2 \quad m_1 \leq m_2}{C \vdash [n_1 .. m_1] \leq [n_2 .. m_2]}$$

3.3.12 Tag Types

The **tag type** $deftype_1$ matches the **tag type** $deftype_2$ if:

- The defined type $deftype_1$ matches the defined type $deftype_2$.
- The defined type $deftype_2$ matches the defined type $deftype_1$.

$$\frac{C \vdash deftype_1 \leq deftype_2 \quad C \vdash deftype_2 \leq deftype_1}{C \vdash deftype_1 \leq deftype_2}$$

Note

Although the conclusion of this rule looks identical to its premise, they in fact describe different relations: the premise invokes subtyping on defined types, while the conclusion defines it on tag types that happen to be expressed as defined types.

3.3.13 Global Types

The **global type** $(mut_1^? valtype_1)$ matches the **global type** $(mut_2^? valtype_2)$ if:

- The value type $valtype_1$ matches the value type $valtype_2$.
- Either:
 - $mut_1^?$ is absent.
 - $mut_2^?$ is absent.
- Or:
 - $mut_1^?$ is of the form `mut`.
 - $mut_2^?$ is of the form `mut`.
 - The value type $valtype_2$ matches the value type $valtype_1$.

$$\frac{C \vdash valtype_1 \leq valtype_2}{C \vdash valtype_1 \leq valtype_2} \quad \frac{C \vdash valtype_1 \leq valtype_2 \quad C \vdash valtype_2 \leq valtype_1}{C \vdash mut \ valtype_1 \leq mut \ valtype_2}$$

3.3.14 Memory Types

The memory type (*addrtype limits₁ page*) matches the memory type (*addrtype limits₂ page*) if:

- The limits range *limits₁* matches the limits range *limits₂*.

$$\frac{C \vdash \text{limits}_1 \leq \text{limits}_2}{C \vdash \text{addrtype limits}_1 \text{ page} \leq \text{addrtype limits}_2 \text{ page}}$$

3.3.15 Table Types

The table type (*addrtype limits₁ reftype₁*) matches the table type (*addrtype limits₂ reftype₂*) if:

- The limits range *limits₁* matches the limits range *limits₂*.
- The reference type *reftype₁* matches the reference type *reftype₂*.
- The reference type *reftype₂* matches the reference type *reftype₁*.

$$\frac{C \vdash \text{limits}_1 \leq \text{limits}_2 \quad C \vdash \text{reftype}_1 \leq \text{reftype}_2 \quad C \vdash \text{reftype}_2 \leq \text{reftype}_1}{C \vdash \text{addrtype limits}_1 \text{ reftype}_1 \leq \text{addrtype limits}_2 \text{ reftype}_2}$$

3.3.16 External Types

The external type (*tag tagtype₁*) matches the external type (*tag tagtype₂*) if:

- The tag type *tagtype₁* matches the tag type *tagtype₂*.

$$\frac{C \vdash \text{tagtype}_1 \leq \text{tagtype}_2}{C \vdash \text{tag tagtype}_1 \leq \text{tag tagtype}_2}$$

The external type (*global globaltype₁*) matches the external type (*global globaltype₂*) if:

- The global type *globaltype₁* matches the global type *globaltype₂*.

$$\frac{C \vdash \text{globaltype}_1 \leq \text{globaltype}_2}{C \vdash \text{global globaltype}_1 \leq \text{global globaltype}_2}$$

The external type (*mem memtype₁*) matches the external type (*mem memtype₂*) if:

- The memory type *memtype₁* matches the memory type *memtype₂*.

$$\frac{C \vdash \text{memtype}_1 \leq \text{memtype}_2}{C \vdash \text{mem memtype}_1 \leq \text{mem memtype}_2}$$

The external type (*table tabletype₁*) matches the external type (*table tabletype₂*) if:

- The table type *tabletype₁* matches the table type *tabletype₂*.

$$\frac{C \vdash \text{tabletype}_1 \leq \text{tabletype}_2}{C \vdash \text{table tabletype}_1 \leq \text{table tabletype}_2}$$

The external type (*func deftype₁*) matches the external type (*func deftype₂*) if:

- The defined type *deftype₁* matches the defined type *deftype₂*.

$$\frac{C \vdash \text{deftype}_1 \leq \text{deftype}_2}{C \vdash \text{func deftype}_1 \leq \text{func deftype}_2}$$

3.4 Instructions

Instructions are classified by **instruction types** that describe how they manipulate the **operand stack** and initialize **locals**: A type $t_1^* \rightarrow_{x^*} t_2^*$ describes the required input stack with argument values of types t_1^* that an instruction pops off and the provided output stack with result values of types t_2^* that it pushes back. Moreover, it enumerates the **indices** x^* of locals that have been set by the instruction. In most cases, this is empty.

Note

For example, the instruction `i32.add` has type $i32\ i32 \rightarrow i32$, consuming two `i32` values and producing one. The instruction `(local.set x)` has type $t \rightarrow_x \epsilon$, provided t is the type declared for the local x .

Typing extends to **instruction sequences** $instr^*$. Such a sequence has an instruction type $t_1^* \rightarrow_{x^*} t_2^*$ if the accumulative effect of executing the instructions is consuming values of types t_1^* off the operand stack, pushing new values of types t_2^* , and setting all locals x^* .

For some instructions, the typing rules do not fully constrain the type, and therefore allow for multiple types. Such instructions are called *polymorphic*. Two degrees of polymorphism can be distinguished:

- *value-polymorphic*: the **value type** t of one or several individual operands is unconstrained. That is the case for all **parametric instructions** like `drop` and `select`.
- *stack-polymorphic*: the entire (or most of the) **instruction type** $t_1^* \rightarrow t_2^*$ of the instruction is unconstrained. That is the case for all **control instructions** that perform an *unconditional control transfer*, such as `unreachable`, `br`, or `return`.

In both cases, the unconstrained types or type sequences can be chosen arbitrarily, as long as they meet the constraints imposed for the surrounding parts of the program.

Note

For example, the `select` instruction is valid with type $t\ t\ i32 \rightarrow t$, for any possible **number type** t . Consequently, both instruction sequences

$$(i32.const\ 1)\ (i32.const\ 2)\ (i32.const\ 3)\ (select)$$

and

$$(f64.const\ +64)\ (f64.const\ +64)\ (f64.const\ +64)\ (select)$$

are valid, with t in the typing of `select` being instantiated to `i32` or `f64`, respectively.

The `unreachable` instruction is stack-polymorphic, and hence valid with type $t_1^* \rightarrow t_2^*$ for any possible sequences of value types t_1^* and t_2^* . Consequently,

$$(unreachable)\ (i32.add)$$

is valid by assuming type $\epsilon \rightarrow i32$ for the `unreachable` instruction. In contrast,

$$(unreachable)\ (i64.const\ 0)\ (i32.add)$$

is invalid, because there is no possible type to pick for the `unreachable` instruction that would make the sequence well-typed.

The **Appendix** describes a type checking **algorithm** that efficiently implements validation of instruction sequences as prescribed by the rules given here.

3.4.1 Parametric Instructions

`nop`

The instruction `nop` is valid with the instruction type $\epsilon \rightarrow \epsilon$.

$$\overline{C \vdash \text{nop} : \epsilon \rightarrow \epsilon}$$

`unreachable`

The instruction `unreachable` is valid with the instruction type $t_1^* \rightarrow t_2^*$ if:

- The instruction type $t_1^* \rightarrow t_2^*$ is valid.

$$\frac{C \vdash t_1^* \rightarrow t_2^* : \text{ok}}{C \vdash \text{unreachable} : t_1^* \rightarrow t_2^*}$$

Note

The `unreachable` instruction is [stack-polymorphic](#).

`drop`

The instruction `drop` is valid with the instruction type $t \rightarrow \epsilon$ if:

- The value type t is valid.

$$\frac{C \vdash t : \text{ok}}{C \vdash \text{drop} : t \rightarrow \epsilon}$$

Note

Both `drop` and `select` without annotation are [value-polymorphic](#) instructions.

`select` $(t^*)^?$

The instruction `(select valtype?)` is valid with the instruction type $t \text{ i32} \rightarrow t$ if:

- The value type t is valid.
- Either:
 - The value type sequence *valtype*[?] is of the form t .
- Or:
 - The value type sequence *valtype*[?] is absent.
 - The value type t matches the value type t' .
 - The value type t' is of the form *numtype* or t' is of the form *vectype*.

$$\frac{C \vdash t : \text{ok}}{C \vdash \text{select } t : t \text{ i32} \rightarrow t} \quad \frac{C \vdash t : \text{ok} \quad C \vdash t \leq t' \quad t' = \text{numtype} \vee t' = \text{vectype}}{C \vdash \text{select} : t \text{ i32} \rightarrow t}$$

Note

In future versions of WebAssembly, `select` may allow more than one value per choice.

3.4.2 Control Instructions

block *blocktype instr**

The instruction (block *bt instr**) is valid with the instruction type $t_1^* \rightarrow t_2^*$ if:

- The block type *bt* is valid as the instruction type $t_1^* \rightarrow t_2^*$.
- Let C' be the same context as C , but with the result type sequence t_2^* prepended to the field *labels*.
- Under the context C' , the instruction sequence *instr** is valid with the instruction type $t_1^* \rightarrow_{x^*} t_2^*$.

$$\frac{C \vdash bt : t_1^* \rightarrow t_2^* \quad \{\text{labels}(t_2^*)\} \oplus C \vdash instr^* : t_1^* \rightarrow_{x^*} t_2^*}{C \vdash \text{block } bt \text{ } instr^* : t_1^* \rightarrow t_2^*}$$

Note

The notation $\{\text{labels}(t^*)\} \oplus C$ inserts the new label type at index 0, shifting all others. The same applies to all other block instructions.

loop *blocktype instr**

The instruction (loop *bt instr**) is valid with the instruction type $t_1^* \rightarrow t_2^*$ if:

- The block type *bt* is valid as the instruction type $t_1^* \rightarrow t_2^*$.
- Let C' be the same context as C , but with the result type sequence t_1^* prepended to the field *labels*.
- Under the context C' , the instruction sequence *instr** is valid with the instruction type $t_1^* \rightarrow_{x^*} t_2^*$.

$$\frac{C \vdash bt : t_1^* \rightarrow t_2^* \quad \{\text{labels}(t_1^*)\} \oplus C \vdash instr^* : t_1^* \rightarrow_{x^*} t_2^*}{C \vdash \text{loop } bt \text{ } instr^* : t_1^* \rightarrow t_2^*}$$

if *blocktype instr*_1* else *instr*_2*

The instruction (if *bt instr*_1* else *instr*_2*) is valid with the instruction type $t_1^* \text{ i32 } \rightarrow t_2^*$ if:

- The block type *bt* is valid as the instruction type $t_1^* \rightarrow t_2^*$.
- Let C' be the same context as C , but with the result type sequence t_2^* prepended to the field *labels*.
- Under the context C' , the instruction sequence *instr*_1* is valid with the instruction type $t_1^* \rightarrow_{x_1^*} t_2^*$.
- Under the context C' , the instruction sequence *instr*_2* is valid with the instruction type $t_1^* \rightarrow_{x_2^*} t_2^*$.

$$\frac{C \vdash bt : t_1^* \rightarrow t_2^* \quad \{\text{labels}(t_2^*)\} \oplus C \vdash instr_1^* : t_1^* \rightarrow_{x_1^*} t_2^* \quad \{\text{labels}(t_2^*)\} \oplus C \vdash instr_2^* : t_1^* \rightarrow_{x_2^*} t_2^*}{C \vdash \text{if } bt \text{ } instr_1^* \text{ else } instr_2^* : t_1^* \text{ i32 } \rightarrow t_2^*}$$

br *l*

The instruction (br *l*) is valid with the instruction type $t_1^* t^* \rightarrow t_2^*$ if:

- The label $C.\text{labels}[l]$ exists.
- The label $C.\text{labels}[l]$ is of the form t^* .
- The instruction type $t_1^* \rightarrow t_2^*$ is valid.

$$\frac{C.\text{labels}[l] = t^* \quad C \vdash t_1^* \rightarrow t_2^* : \text{ok}}{C \vdash \text{br } l : t_1^* t^* \rightarrow t_2^*}$$

Note

The **label index** space in the **context** C contains the most recent label first, so that $C.\text{labels}[l]$ performs a relative lookup as expected. This applies to other branch instructions as well.

The `br` instruction is **stack-polymorphic**.

br_if l

The instruction `(br_if l)` is valid with the instruction type $t^* \text{ i32} \rightarrow t^*$ if:

- The label $C.\text{labels}[l]$ exists.
- The label $C.\text{labels}[l]$ is of the form t^* .

$$\frac{C.\text{labels}[l] = t^*}{C \vdash \text{br_if } l : t^* \text{ i32} \rightarrow t^*}$$

br_table $l^* l_N$

The instruction `(br_table $l^* l'$)` is valid with the instruction type $t_1^* t^* \text{ i32} \rightarrow t_2^*$ if:

- For all l in l^* :
 - The label $C.\text{labels}[l]$ exists.
 - The result type t^* matches the label $C.\text{labels}[l]$.
- The label $C.\text{labels}[l']$ exists.
- The result type t^* matches the label $C.\text{labels}[l']$.
- The instruction type $t_1^* t^* \text{ i32} \rightarrow t_2^*$ is valid.

$$\frac{(C \vdash t^* \leq C.\text{labels}[l])^* \quad C \vdash t^* \leq C.\text{labels}[l'] \quad C \vdash t_1^* t^* \text{ i32} \rightarrow t_2^* : \text{ok}}{C \vdash \text{br_table } l^* l' : t_1^* t^* \text{ i32} \rightarrow t_2^*}$$

Note

The `br_table` instruction is **stack-polymorphic**.

Furthermore, the **result type** t^* is also chosen non-deterministically in this rule. Although it may seem necessary to compute t^* as the greatest lower bound of all label types in practice, a simple **sequential algorithm** does not require this.

br_on_null l

The instruction `(br_on_null l)` is valid with the instruction type $t^* (\text{ref null } ht) \rightarrow t^* (\text{ref } ht)$ if:

- The label $C.\text{labels}[l]$ exists.
- The label $C.\text{labels}[l]$ is of the form t^* .
- The heap type ht is valid.

$$\frac{C.\text{labels}[l] = t^* \quad C \vdash ht : \text{ok}}{C \vdash \text{br_on_null } l : t^* (\text{ref null } ht) \rightarrow t^* (\text{ref } ht)}$$

br_on_non_null l

The instruction `(br_on_non_null l)` is valid with the instruction type $t^* (\text{ref null } ht) \rightarrow t^*$ if:

- The label $C.\text{labels}[l]$ exists.
- The label $C.\text{labels}[l]$ is of the form $t^* (\text{ref null}^? ht)$.

$$\frac{C.\text{labels}[l] = t^* (\text{ref null}^? ht)}{C \vdash \text{br_on_non_null } l : t^* (\text{ref null } ht) \rightarrow t^*}$$

$\text{br_on_cast } l \ rt_1 \ rt_2$

The instruction $(\text{br_on_cast } l \ rt_1 \ rt_2)$ is valid with the instruction type $t^* \ rt_1 \rightarrow t^* \ \text{reftype}$ if:

- The label $C.\text{labels}[l]$ exists.
- The label $C.\text{labels}[l]$ is of the form $t^* \ rt$.
- The reference type rt_1 is valid.
- The reference type rt_2 is valid.
- The reference type rt_2 matches the reference type rt_1 .
- The reference type rt_2 matches the reference type rt .
- The reference type reftype is $rt_1 \setminus rt_2$.

$$\frac{C.\text{labels}[l] = t^* \ rt \quad C \vdash rt_1 : \text{ok} \quad C \vdash rt_2 : \text{ok} \quad C \vdash rt_2 \leq rt_1 \quad C \vdash rt_2 \leq rt}{C \vdash \text{br_on_cast } l \ rt_1 \ rt_2 : t^* \ rt_1 \rightarrow t^* (rt_1 \setminus rt_2)}$$

$\text{br_on_cast_fail } l \ rt_1 \ rt_2$

The instruction $(\text{br_on_cast_fail } l \ rt_1 \ rt_2)$ is valid with the instruction type $t^* \ rt_1 \rightarrow t^* \ rt_2$ if:

- The label $C.\text{labels}[l]$ exists.
- The label $C.\text{labels}[l]$ is of the form $t^* \ rt$.
- The reference type rt_1 is valid.
- The reference type rt_2 is valid.
- The reference type rt_2 matches the reference type rt_1 .
- The reference type $rt_1 \setminus rt_2$ matches the reference type rt .

$$\frac{C.\text{labels}[l] = t^* \ rt \quad C \vdash rt_1 : \text{ok} \quad C \vdash rt_2 : \text{ok} \quad C \vdash rt_2 \leq rt_1 \quad C \vdash rt_1 \setminus rt_2 \leq rt}{C \vdash \text{br_on_cast_fail } l \ rt_1 \ rt_2 : t^* \ rt_1 \rightarrow t^* \ rt_2}$$

$\text{call } x$

The instruction $(\text{call } x)$ is valid with the instruction type $t_1^* \rightarrow t_2^*$ if:

- The function $C.\text{funcs}[x]$ exists.
- The expansion of $C.\text{funcs}[x]$ is $(\text{func } t_1^* \rightarrow t_2^*)$.

$$\frac{C.\text{funcs}[x] \approx \text{func } t_1^* \rightarrow t_2^*}{C \vdash \text{call } x : t_1^* \rightarrow t_2^*}$$

$\text{call_ref } x$

The instruction $(\text{call_ref } x)$ is valid with the instruction type $t_1^* (\text{ref null } x) \rightarrow t_2^*$ if:

- The type $C.\text{types}[x]$ exists.
- The expansion of $C.\text{types}[x]$ is $(\text{func } t_1^* \rightarrow t_2^*)$.

$$\frac{C.\text{types}[x] \approx \text{func } t_1^* \rightarrow t_2^*}{C \vdash \text{call_ref } x : t_1^* (\text{ref null } x) \rightarrow t_2^*}$$

`call_indirect x y`

The instruction `(call_indirect x y)` is valid with the instruction type $t_1^* \text{ at } \rightarrow t_2^*$ if:

- The table $C.\text{tables}[x]$ exists.
- The table $C.\text{tables}[x]$ is of the form $(\text{at } \text{lim } rt)$.
- The reference type rt matches the reference type (ref null func) .
- The type $C.\text{types}[y]$ exists.
- The expansion of $C.\text{types}[y]$ is $(\text{func } t_1^* \rightarrow t_2^*)$.

$$\frac{C.\text{tables}[x] = \text{at } \text{lim } rt \quad C \vdash rt \leq (\text{ref null func}) \quad C.\text{types}[y] \approx \text{func } t_1^* \rightarrow t_2^*}{C \vdash \text{call_indirect } x y : t_1^* \text{ at } \rightarrow t_2^*}$$

`return`

The instruction `return` is valid with the instruction type $t_1^* t^* \rightarrow t_2^*$ if:

- The result type $C.\text{return}$ is of the form t^* .
- The instruction type $t_1^* \rightarrow t_2^*$ is valid.

$$\frac{C.\text{return} = (t^*) \quad C \vdash t_1^* \rightarrow t_2^* : \text{ok}}{C \vdash \text{return} : t_1^* t^* \rightarrow t_2^*}$$

Note

The `return` instruction is [stack-polymorphic](#).

$C.\text{return}$ is absent (set to ϵ) when validating an [expression](#) that is not a function body. This differs from it being set to the empty result type $[\epsilon]$, which is the case for functions not returning anything.

`return_call x`

The instruction `(return_call x)` is valid with the instruction type $t_3^* t_1^* \rightarrow t_4^*$ if:

- The function $C.\text{funcs}[x]$ exists.
- The expansion of $C.\text{funcs}[x]$ is $(\text{func } t_1^* \rightarrow t_2^*)$.
- The result type $C.\text{return}$ is of the form $t_2'^*$.
- The result type t_2^* matches the result type $t_2'^*$.
- The instruction type $t_3^* \rightarrow t_4^*$ is valid.

$$\frac{C.\text{funcs}[x] \approx \text{func } t_1^* \rightarrow t_2^* \quad C.\text{return} = (t_2'^*) \quad C \vdash t_2^* \leq t_2'^* \quad C \vdash t_3^* \rightarrow t_4^* : \text{ok}}{C \vdash \text{return_call } x : t_3^* t_1^* \rightarrow t_4^*}$$

Note

The `return_call` instruction is [stack-polymorphic](#).

`return_call_ref x`

The instruction `(return_call_ref x)` is valid with the instruction type $t_3^* t_1^* (\text{ref null } x) \rightarrow t_4^*$ if:

- The type $C.\text{types}[x]$ exists.
- The expansion of $C.\text{types}[x]$ is $(\text{func } t_1^* \rightarrow t_2^*)$.
- The result type $C.\text{return}$ is of the form $t_2'^*$.
- The result type t_2^* matches the result type $t_2'^*$.

- The instruction type $t_3^* \rightarrow t_4^*$ is valid.

$$\frac{C.\text{types}[x] \approx \text{func } t_1^* \rightarrow t_2^* \quad C.\text{return} = (t_2'^*) \quad C \vdash t_2^* \leq t_2'^* \quad C \vdash t_3^* \rightarrow t_4^* : \text{ok}}{C \vdash \text{return_call_ref } x : t_3^* t_1^* (\text{ref null } x) \rightarrow t_4^*}$$

Note

The `return_call_ref` instruction is [stack-polymorphic](#).

`return_call_indirect x y`

The instruction (`return_call_indirect x y`) is valid with the instruction type $t_3^* t_1^* \text{ at } \rightarrow t_4^*$ if:

- The table $C.\text{tables}[x]$ exists.
- The table $C.\text{tables}[x]$ is of the form $(\text{at } \text{lim } rt)$.
- The reference type rt matches the reference type (ref null func) .
- The type $C.\text{types}[y]$ exists.
- The expansion of $C.\text{types}[y]$ is $(\text{func } t_1^* \rightarrow t_2^*)$.
- The result type $C.\text{return}$ is of the form $t_2'^*$.
- The result type t_2^* matches the result type $t_2'^*$.
- The instruction type $t_3^* \rightarrow t_4^*$ is valid.

$$\frac{C.\text{tables}[x] = \text{at } \text{lim } rt \quad C \vdash rt \leq (\text{ref null func}) \quad C.\text{types}[y] \approx \text{func } t_1^* \rightarrow t_2^* \quad C.\text{return} = (t_2'^*) \quad C \vdash t_2^* \leq t_2'^* \quad C \vdash t_3^* \rightarrow t_4^* : \text{ok}}{C \vdash \text{return_call_indirect } x y : t_3^* t_1^* \text{ at } \rightarrow t_4^*}$$

Note

The `return_call_indirect` instruction is [stack-polymorphic](#).

`throw x`

The instruction (`throw x`) is valid with the instruction type $t_1^* t^* \rightarrow t_2^*$ if:

- The tag $C.\text{tags}[x]$ exists.
- The expansion of $C.\text{tags}[x]$ is $(\text{func } t^* \rightarrow)$.
- The instruction type $t_1^* \rightarrow t_2^*$ is valid.

$$\frac{C.\text{tags}[x] \approx \text{func } t^* \rightarrow \epsilon \quad C \vdash t_1^* \rightarrow t_2^* : \text{ok}}{C \vdash \text{throw } x : t_1^* t^* \rightarrow t_2^*}$$

Note

The `throw` instruction is [stack-polymorphic](#).

`throw_ref`

The instruction `throw_ref` is valid with the instruction type $t_1^* (\text{ref null exn}) \rightarrow t_2^*$ if:

- The instruction type $t_1^* \rightarrow t_2^*$ is valid.

$$\frac{C \vdash t_1^* \rightarrow t_2^* : \text{ok}}{C \vdash \text{throw_ref} : t_1^* (\text{ref null exn}) \rightarrow t_2^*}$$

Note

The `throw_ref` instruction is [stack-polymorphic](#).

`try_table blocktype catch* instr*`

The instruction (`try_table bt catch* instr*`) is valid with the instruction type $t_1^* \rightarrow t_2^*$ if:

- The block type *bt* is valid as the instruction type $t_1^* \rightarrow t_2^*$.
- Let C' be the same context as C , but with the result type sequence t_2^* prepended to the field `labels`.
- Under the context C' , the instruction sequence *instr** is valid with the instruction type $t_1^* \rightarrow_{x^*} t_2^*$.
- For all *catch* in *catch**:
 - The catch clause *catch* is valid.

$$\frac{C \vdash bt : t_1^* \rightarrow t_2^* \quad \{\text{labels}(t_2^*)\} \oplus C \vdash \text{instr}^* : t_1^* \rightarrow_{x^*} t_2^* \quad (C \vdash \text{catch} : \text{ok})^*}{C \vdash \text{try_table } bt \text{ catch}^* \text{ instr}^* : t_1^* \rightarrow t_2^*}$$

`catch x l`

The catch clause (`catch x l`) is valid if:

- The tag $C.\text{tags}[x]$ exists.
- The expansion of $C.\text{tags}[x]$ is $(\text{func } t^* \rightarrow)$.
- The label $C.\text{labels}[l]$ exists.
- The result type t^* matches the label $C.\text{labels}[l]$.

$$\frac{C.\text{tags}[x] \approx \text{func } t^* \rightarrow \epsilon \quad C \vdash t^* \leq C.\text{labels}[l]}{C \vdash \text{catch } x \text{ } l : \text{ok}}$$

`catch_ref x l`

The catch clause (`catch_ref x l`) is valid if:

- The tag $C.\text{tags}[x]$ exists.
- The expansion of $C.\text{tags}[x]$ is $(\text{func } t^* \rightarrow)$.
- The label $C.\text{labels}[l]$ exists.
- The result type t^* (`ref exn`) matches the label $C.\text{labels}[l]$.

$$\frac{C.\text{tags}[x] \approx \text{func } t^* \rightarrow \epsilon \quad C \vdash t^* (\text{ref exn}) \leq C.\text{labels}[l]}{C \vdash \text{catch_ref } x \text{ } l : \text{ok}}$$

`catch_all l`

The catch clause (`catch_all l`) is valid if:

- The label $C.\text{labels}[l]$ exists.
- The result type ϵ matches the label $C.\text{labels}[l]$.

$$\frac{C \vdash \epsilon \leq C.\text{labels}[l]}{C \vdash \text{catch_all } l : \text{ok}}$$

`catch_all_ref l`

The `catch` clause (`catch_all_ref l`) is valid if:

- The label $C.labels[l]$ exists.
- The result type (`ref exn`) matches the label $C.labels[l]$.

$$\frac{C \vdash (\text{ref exn}) \leq C.labels[l]}{C \vdash \text{catch_all_ref } l : \text{ok}}$$

3.4.3 Variable Instructions

`local.get x`

The instruction (`local.get x`) is valid with the instruction type $\epsilon \rightarrow t$ if:

- The local $C.locals[x]$ exists.
- The local $C.locals[x]$ is of the form (`set t`).

$$\frac{C.locals[x] = \text{set } t}{C \vdash \text{local.get } x : \epsilon \rightarrow t}$$

`local.set x`

The instruction (`local.set x`) is valid with the instruction type $t \rightarrow_x \epsilon$ if:

- The local $C.locals[x]$ exists.
- The local $C.locals[x]$ is of the form (`init t`).

$$\frac{C.locals[x] = \text{init } t}{C \vdash \text{local.set } x : t \rightarrow_x \epsilon}$$

`local.tee x`

The instruction (`local.tee x`) is valid with the instruction type $t \rightarrow_x t$ if:

- The local $C.locals[x]$ exists.
- The local $C.locals[x]$ is of the form (`init t`).

$$\frac{C.locals[x] = \text{init } t}{C \vdash \text{local.tee } x : t \rightarrow_x t}$$

`global.get x`

The instruction (`global.get x`) is valid with the instruction type $\epsilon \rightarrow t$ if:

- The global $C.globals[x]$ exists.
- The global $C.globals[x]$ is of the form (`mut? t`).

$$\frac{C.globals[x] = \text{mut}^? t}{C \vdash \text{global.get } x : \epsilon \rightarrow t}$$

`global.set x`

The instruction (`global.set x`) is valid with the instruction type $t \rightarrow \epsilon$ if:

- The global $C.globals[x]$ exists.
- The global $C.globals[x]$ is of the form (`mut t`).

$$\frac{C.globals[x] = \text{mut } t}{C \vdash \text{global.set } x : t \rightarrow \epsilon}$$

3.4.4 Table Instructions

`table.get x`

The instruction `(table.get x)` is valid with the instruction type $at \rightarrow rt$ if:

- The table $C.tables[x]$ exists.
- The table $C.tables[x]$ is of the form $(at \lim rt)$.

$$\frac{C.tables[x] = at \lim rt}{C \vdash \text{table.get } x : at \rightarrow rt}$$

`table.set x`

The instruction `(table.set x)` is valid with the instruction type $at \ rt \rightarrow \epsilon$ if:

- The table $C.tables[x]$ exists.
- The table $C.tables[x]$ is of the form $(at \lim rt)$.

$$\frac{C.tables[x] = at \lim rt}{C \vdash \text{table.set } x : at \ rt \rightarrow \epsilon}$$

`table.size x`

The instruction `(table.size x)` is valid with the instruction type $\epsilon \rightarrow at$ if:

- The table $C.tables[x]$ exists.
- The table $C.tables[x]$ is of the form $(at \lim rt)$.

$$\frac{C.tables[x] = at \lim rt}{C \vdash \text{table.size } x : \epsilon \rightarrow at}$$

`table.grow x`

The instruction `(table.grow x)` is valid with the instruction type $rt \ at \rightarrow i32$ if:

- The table $C.tables[x]$ exists.
- The table $C.tables[x]$ is of the form $(at \lim rt)$.

$$\frac{C.tables[x] = at \lim rt}{C \vdash \text{table.grow } x : rt \ at \rightarrow i32}$$

`table.fill x`

The instruction `(table.fill x)` is valid with the instruction type $at \ rt \ at \rightarrow \epsilon$ if:

- The table $C.tables[x]$ exists.
- The table $C.tables[x]$ is of the form $(at \lim rt)$.

$$\frac{C.tables[x] = at \lim rt}{C \vdash \text{table.fill } x : at \ rt \ at \rightarrow \epsilon}$$

`table.copy $x \ y$`

The instruction `(table.copy $x_1 \ x_2$)` is valid with the instruction type $at_1 \ at_2 \ addrtype \rightarrow \epsilon$ if:

- The table $C.tables[x_1]$ exists.
- The table $C.tables[x_1]$ is of the form $(at_1 \ lim_1 \ rt_1)$.
- The table $C.tables[x_2]$ exists.
- The table $C.tables[x_2]$ is of the form $(at_2 \ lim_2 \ rt_2)$.
- The reference type rt_2 matches the reference type rt_1 .

- The address type $addrtype$ is $\min(at_1, at_2)$.

$$\frac{C.tables[x_1] = at_1 \text{ lim}_1 rt_1 \quad C.tables[x_2] = at_2 \text{ lim}_2 rt_2 \quad C \vdash rt_2 \leq rt_1}{C \vdash \text{table.copy } x_1 x_2 : at_1 at_2 \min(at_1, at_2) \rightarrow \epsilon}$$

$\text{table.init } x y$

The instruction $(\text{table.init } x y)$ is valid with the instruction type $at \text{ i32 i32} \rightarrow \epsilon$ if:

- The table $C.tables[x]$ exists.
- The table $C.tables[x]$ is of the form $(at \text{ lim } rt_1)$.
- The element segment $C.elems[y]$ exists.
- The element segment $C.elems[y]$ is of the form rt_2 .
- The reference type rt_2 matches the reference type rt_1 .

$$\frac{C.tables[x] = at \text{ lim } rt_1 \quad C.elems[y] = rt_2 \quad C \vdash rt_2 \leq rt_1}{C \vdash \text{table.init } x y : at \text{ i32 i32} \rightarrow \epsilon}$$

$\text{elem.drop } x$

The instruction $(\text{elem.drop } x)$ is valid with the instruction type $\epsilon \rightarrow \epsilon$ if:

- The element segment $C.elems[x]$ exists.

$$\frac{C.elems[x] = rt}{C \vdash \text{elem.drop } x : \epsilon \rightarrow \epsilon}$$

3.4.5 Memory Instructions

$t.\text{load } x \text{ memarg}$

The instruction $(t.\text{load } x \text{ memarg})$ is valid with the instruction type $at \rightarrow nt$ if:

- The memory $C.mems[x]$ exists.
- The memory $C.mems[x]$ is of the form $(at \text{ lim page})$.
- $2^{\text{memarg.align}}$ is less than or equal to $|nt|/8$.

$$\frac{C.mems[x] = at \text{ lim page} \quad 2^{\text{memarg.align}} \leq |nt|/8}{C \vdash t.\text{load } x \text{ memarg} : at \rightarrow nt}$$

$t.\text{loadN_sx } x \text{ memarg}$

The instruction $(t.\text{loadN_sx } x \text{ memarg})$ is valid with the instruction type $at \rightarrow iN$ if:

- The memory $C.mems[x]$ exists.
- The memory $C.mems[x]$ is of the form $(at \text{ lim page})$.
- $2^{\text{memarg.align}}$ is less than or equal to $M/8$.

$$\frac{C.mems[x] = at \text{ lim page} \quad 2^{\text{memarg.align}} \leq M/8}{C \vdash t.\text{loadN_sx } x \text{ memarg} : at \rightarrow iN}$$

$t.\text{store } x \text{ memarg}$

The instruction $(t.\text{store } x \text{ memarg})$ is valid with the instruction type $at nt \rightarrow \epsilon$ if:

- The memory $C.mems[x]$ exists.
- The memory $C.mems[x]$ is of the form $(at \text{ lim page})$.
- $2^{\text{memarg.align}}$ is less than or equal to $|nt|/8$.

$$\frac{C.\text{mems}[x] = \text{at } \text{lim page} \quad 2^{\text{memarg.align}} \leq |\text{nt}|/8}{C \vdash \text{nt.store } x \text{ memarg} : \text{at nt} \rightarrow \epsilon}$$

t.storeN x memarg

The instruction (*in.storeM x memarg*) is valid with the instruction type $\text{at in} \rightarrow \epsilon$ if:

- The memory $C.\text{mems}[x]$ exists.
- The memory $C.\text{mems}[x]$ is of the form (*at lim page*).
- $2^{\text{memarg.align}}$ is less than or equal to $M/8$.

$$\frac{C.\text{mems}[x] = \text{at } \text{lim page} \quad 2^{\text{memarg.align}} \leq M/8}{C \vdash \text{in.storeM } x \text{ memarg} : \text{at in} \rightarrow \epsilon}$$

v128.load x memarg

The instruction (*v128.load x memarg*) is valid with the instruction type $\text{at} \rightarrow \text{v128}$ if:

- The memory $C.\text{mems}[x]$ exists.
- The memory $C.\text{mems}[x]$ is of the form (*at lim page*).
- $2^{\text{memarg.align}}$ is less than or equal to $|\text{v128}|/8$.

$$\frac{C.\text{mems}[x] = \text{at } \text{lim page} \quad 2^{\text{memarg.align}} \leq |\text{v128}|/8}{C \vdash \text{v128.load } x \text{ memarg} : \text{at} \rightarrow \text{v128}}$$

v128.loadNxM_sx x memarg

The instruction (*v128.loadMxN_sx x memarg*) is valid with the instruction type $\text{at} \rightarrow \text{v128}$ if:

- The memory $C.\text{mems}[x]$ exists.
- The memory $C.\text{mems}[x]$ is of the form (*at lim page*).
- $2^{\text{memarg.align}}$ is less than or equal to $M/8 \cdot N$.

$$\frac{C.\text{mems}[x] = \text{at } \text{lim page} \quad 2^{\text{memarg.align}} \leq M/8 \cdot N}{C \vdash \text{v128.loadMxN_sx } x \text{ memarg} : \text{at} \rightarrow \text{v128}}$$

v128.loadN_splat x memarg

The instruction (*v128.loadN_splat x memarg*) is valid with the instruction type $\text{at} \rightarrow \text{v128}$ if:

- The memory $C.\text{mems}[x]$ exists.
- The memory $C.\text{mems}[x]$ is of the form (*at lim page*).
- $2^{\text{memarg.align}}$ is less than or equal to $N/8$.

$$\frac{C.\text{mems}[x] = \text{at } \text{lim page} \quad 2^{\text{memarg.align}} \leq N/8}{C \vdash \text{v128.loadN_splat } x \text{ memarg} : \text{at} \rightarrow \text{v128}}$$

v128.loadN_zero x memarg

The instruction (*v128.loadN_zero x memarg*) is valid with the instruction type $\text{at} \rightarrow \text{v128}$ if:

- The memory $C.\text{mems}[x]$ exists.
- The memory $C.\text{mems}[x]$ is of the form (*at lim page*).
- $2^{\text{memarg.align}}$ is less than or equal to $N/8$.

$$\frac{C.\text{mems}[x] = \text{at } \text{lim page} \quad 2^{\text{memarg.align}} \leq N/8}{C \vdash \text{v128.loadN_zero } x \text{ memarg} : \text{at} \rightarrow \text{v128}}$$

$\text{v128.loadN_lane } x \text{ memarg laneid}x$

The instruction ($\text{v128.loadN_lane } x \text{ memarg } i$) is valid with the instruction type $at \text{ v128} \rightarrow \text{v128}$ if:

- The memory $C.\text{mems}[x]$ exists.
- The memory $C.\text{mems}[x]$ is of the form $(at \text{ lim page})$.
- $2^{\text{memarg.align}}$ is less than or equal to $N/8$.
- i is less than $128/N$.

$$\frac{C.\text{mems}[x] = at \text{ lim page} \quad 2^{\text{memarg.align}} \leq N/8 \quad i < 128/N}{C \vdash \text{v128.loadN_lane } x \text{ memarg } i : at \text{ v128} \rightarrow \text{v128}}$$

$\text{v128.store } x \text{ memarg}$

The instruction ($\text{v128.store } x \text{ memarg}$) is valid with the instruction type $at \text{ v128} \rightarrow \epsilon$ if:

- The memory $C.\text{mems}[x]$ exists.
- The memory $C.\text{mems}[x]$ is of the form $(at \text{ lim page})$.
- $2^{\text{memarg.align}}$ is less than or equal to $|v128|/8$.

$$\frac{C.\text{mems}[x] = at \text{ lim page} \quad 2^{\text{memarg.align}} \leq |v128|/8}{C \vdash \text{v128.store } x \text{ memarg} : at \text{ v128} \rightarrow \epsilon}$$

$\text{v128.storeN_lane } x \text{ memarg laneid}x$

The instruction ($\text{v128.storeN_lane } x \text{ memarg } i$) is valid with the instruction type $at \text{ v128} \rightarrow \epsilon$ if:

- The memory $C.\text{mems}[x]$ exists.
- The memory $C.\text{mems}[x]$ is of the form $(at \text{ lim page})$.
- $2^{\text{memarg.align}}$ is less than or equal to $N/8$.
- i is less than $128/N$.

$$\frac{C.\text{mems}[x] = at \text{ lim page} \quad 2^{\text{memarg.align}} \leq N/8 \quad i < 128/N}{C \vdash \text{v128.storeN_lane } x \text{ memarg } i : at \text{ v128} \rightarrow \epsilon}$$

$\text{memory.size } x$

The instruction ($\text{memory.size } x$) is valid with the instruction type $\epsilon \rightarrow at$ if:

- The memory $C.\text{mems}[x]$ exists.
- The memory $C.\text{mems}[x]$ is of the form $(at \text{ lim page})$.

$$\frac{C.\text{mems}[x] = at \text{ lim page}}{C \vdash \text{memory.size } x : \epsilon \rightarrow at}$$

$\text{memory.grow } x$

The instruction ($\text{memory.grow } x$) is valid with the instruction type $at \rightarrow at$ if:

- The memory $C.\text{mems}[x]$ exists.
- The memory $C.\text{mems}[x]$ is of the form $(at \text{ lim page})$.

$$\frac{C.\text{mems}[x] = at \text{ lim page}}{C \vdash \text{memory.grow } x : at \rightarrow at}$$

`memory.fill x`

The instruction (`memory.fill x`) is valid with the instruction type $at\ i32\ at \rightarrow \epsilon$ if:

- The memory $C.mems[x]$ exists.
- The memory $C.mems[x]$ is of the form $(at\ lim\ page)$.

$$\frac{C.mems[x] = at\ lim\ page}{C \vdash memory.fill\ x : at\ i32\ at \rightarrow \epsilon}$$

`memory.copy x y`

The instruction (`memory.copy x1 x2`) is valid with the instruction type $at_1\ at_2\ addrtype \rightarrow \epsilon$ if:

- The memory $C.mems[x_1]$ exists.
- The memory $C.mems[x_1]$ is of the form $(at_1\ lim_1\ page)$.
- The memory $C.mems[x_2]$ exists.
- The memory $C.mems[x_2]$ is of the form $(at_2\ lim_2\ page)$.
- The address type $addrtype$ is $\min(at_1, at_2)$.

$$\frac{C.mems[x_1] = at_1\ lim_1\ page \quad C.mems[x_2] = at_2\ lim_2\ page}{C \vdash memory.copy\ x_1\ x_2 : at_1\ at_2\ \min(at_1, at_2) \rightarrow \epsilon}$$

`memory.init x y`

The instruction (`memory.init x y`) is valid with the instruction type $at\ i32\ i32 \rightarrow \epsilon$ if:

- The memory $C.mems[x]$ exists.
- The memory $C.mems[x]$ is of the form $(at\ lim\ page)$.
- The data segment $C.datas[y]$ exists.
- The data segment $C.datas[y]$ is of the form `ok`.

$$\frac{C.mems[x] = at\ lim\ page \quad C.datas[y] = ok}{C \vdash memory.init\ x\ y : at\ i32\ i32 \rightarrow \epsilon}$$

`data.drop x`

The instruction (`data.drop x`) is valid with the instruction type $\epsilon \rightarrow \epsilon$ if:

- The data segment $C.datas[x]$ exists.
- The data segment $C.datas[x]$ is of the form `ok`.

$$\frac{C.datas[x] = ok}{C \vdash data.drop\ x : \epsilon \rightarrow \epsilon}$$

3.4.6 Reference Instructions

`ref.null ht`

The instruction (`ref.null ht`) is valid with the instruction type $\epsilon \rightarrow (\text{ref null } ht)$ if:

- The heap type ht is valid.

$$\frac{C \vdash ht : ok}{C \vdash ref.null\ ht : \epsilon \rightarrow (\text{ref null } ht)}$$

`ref.func x`

The instruction `(ref.func x)` is valid with the instruction type $\epsilon \rightarrow (\text{ref } dt)$ if:

- The function $C.\text{funcs}[x]$ exists.
- The function $C.\text{funcs}[x]$ is of the form dt .
- x is contained in $C.\text{refs}$.

$$\frac{C.\text{funcs}[x] = dt \quad x \in C.\text{refs}}{C \vdash \text{ref.func } x : \epsilon \rightarrow (\text{ref } dt)}$$

`ref.is_null`

The instruction `ref.is_null` is valid with the instruction type $(\text{ref null } ht) \rightarrow i32$ if:

- The heap type ht is valid.

$$\frac{C \vdash ht : \text{ok}}{C \vdash \text{ref.is_null} : (\text{ref null } ht) \rightarrow i32}$$

`ref.as_non_null`

The instruction `ref.as_non_null` is valid with the instruction type $(\text{ref null } ht) \rightarrow (\text{ref } ht)$ if:

- The heap type ht is valid.

$$\frac{C \vdash ht : \text{ok}}{C \vdash \text{ref.as_non_null} : (\text{ref null } ht) \rightarrow (\text{ref } ht)}$$

`ref.eq`

The instruction `ref.eq` is valid with the instruction type $(\text{ref null eq}) (\text{ref null eq}) \rightarrow i32$.

$$\overline{C \vdash \text{ref.eq} : (\text{ref null eq}) (\text{ref null eq}) \rightarrow i32}$$

`ref.test rt`

The instruction `(ref.test rt)` is valid with the instruction type $rt' \rightarrow i32$ if:

- The reference type rt is valid.
- The reference type rt' is valid.
- The reference type rt matches the reference type rt' .

$$\frac{C \vdash rt : \text{ok} \quad C \vdash rt' : \text{ok} \quad C \vdash rt \leq rt'}{C \vdash \text{ref.test } rt : rt' \rightarrow i32}$$

Note

The liberty to pick a supertype rt' allows typing the instruction with the least precise super type of rt as input, that is, the top type in the corresponding heap subtyping hierarchy.

`ref.cast rt`

The instruction `(ref.cast rt)` is valid with the instruction type $rt' \rightarrow rt$ if:

- The reference type rt is valid.
- The reference type rt' is valid.
- The reference type rt matches the reference type rt' .

$$\frac{C \vdash rt : \text{ok} \quad C \vdash rt' : \text{ok} \quad C \vdash rt \leq rt'}{C \vdash \text{ref.cast } rt : rt' \rightarrow rt}$$

Note

The liberty to pick a supertype rt' allows typing the instruction with the least precise super type of rt as input, that is, the top type in the corresponding heap subtyping hierarchy.

3.4.7 Aggregate Reference Instructions

`struct.new x`

The instruction `(struct.new x)` is valid with the instruction type $t^* \rightarrow (\text{ref } x)$ if:

- The type $C.\text{types}[x]$ exists.
- The expansion of $C.\text{types}[x]$ is `(struct (mut? zt)*)`.
- The value type sequence t^* is `unpack(zt)*`.

$$\frac{C.\text{types}[x] \approx \text{struct } (\text{mut}^? \text{ } zt)^*}{C \vdash \text{struct.new } x : \text{unpack}(zt)^* \rightarrow (\text{ref } x)}$$

`struct.new_default x`

The instruction `(struct.new_default x)` is valid with the instruction type $\epsilon \rightarrow (\text{ref } x)$ if:

- The type $C.\text{types}[x]$ exists.
- The expansion of $C.\text{types}[x]$ is `(struct (mut? zt)*)`.
- For all zt in zt^* :
 - A default value for `unpack(zt)` is defined.

$$\frac{C.\text{types}[x] \approx \text{struct } (\text{mut}^? \text{ } zt)^* \quad (\text{default}_{\text{unpack}(zt)} \neq \epsilon)^*}{C \vdash \text{struct.new_default } x : \epsilon \rightarrow (\text{ref } x)}$$

`struct.get_ $sx^?$ x y`

The instruction `(struct.get_ $sx^?$ x i)` is valid with the instruction type `(ref null x) \rightarrow t` if:

- The type $C.\text{types}[x]$ exists.
- The expansion of $C.\text{types}[x]$ is `(struct ft^*)`.
- The length of ft^* is greater than i .
- The field type $ft^*[i]$ is of the form `(mut? zt)`.
- The signedness $sx^?$ is absent if and only if zt is a packed type.
- The value type t is `unpack(zt)`.

$$\frac{C.\text{types}[x] \approx \text{struct } ft^* \quad ft^*[i] = \text{mut}^? \text{ } zt \quad sx^? = \epsilon \Leftrightarrow zt = \text{unpack}(zt)}{C \vdash \text{struct.get_sx}^? \text{ } x \text{ } i : (\text{ref null } x) \rightarrow \text{unpack}(zt)}$$

`struct.set x y`

The instruction `(struct.set x i)` is valid with the instruction type `(ref null x) $t \rightarrow \epsilon$` if:

- The type $C.\text{types}[x]$ exists.
- The expansion of $C.\text{types}[x]$ is `(struct ft^*)`.
- The length of ft^* is greater than i .
- The field type $ft^*[i]$ is of the form `(mut zt)`.

- The value type t is $\text{unpack}(zt)$.

$$\frac{C.\text{types}[x] \approx \text{struct } ft^* \quad ft^*[i] = \text{mut } zt}{C \vdash \text{struct.set } x \ i : (\text{ref null } x) \text{ unpack}(zt) \rightarrow \epsilon}$$

`array.new x`

The instruction `(array.new x)` is valid with the instruction type $t \text{ i32} \rightarrow (\text{ref } x)$ if:

- The type $C.\text{types}[x]$ exists.
- The expansion of $C.\text{types}[x]$ is $(\text{array } (\text{mut}^? zt))$.
- The value type t is $\text{unpack}(zt)$.

$$\frac{C.\text{types}[x] \approx \text{array } (\text{mut}^? zt)}{C \vdash \text{array.new } x : \text{unpack}(zt) \text{ i32} \rightarrow (\text{ref } x)}$$

`array.new_default x`

The instruction `(array.new_default x)` is valid with the instruction type $\text{i32} \rightarrow (\text{ref } x)$ if:

- The type $C.\text{types}[x]$ exists.
- The expansion of $C.\text{types}[x]$ is $(\text{array } (\text{mut}^? zt))$.
- A default value for $\text{unpack}(zt)$ is defined.

$$\frac{C.\text{types}[x] \approx \text{array } (\text{mut}^? zt) \quad \text{default}_{\text{unpack}(zt)} \neq \epsilon}{C \vdash \text{array.new_default } x : \text{i32} \rightarrow (\text{ref } x)}$$

`array.new_fixed $x \ n$`

The instruction `(array.new_fixed $x \ n$)` is valid with the instruction type $t^n \rightarrow (\text{ref } x)$ if:

- The type $C.\text{types}[x]$ exists.
- The expansion of $C.\text{types}[x]$ is $(\text{array } (\text{mut}^? zt))$.
- The value type t is $\text{unpack}(zt)$.

$$\frac{C.\text{types}[x] \approx \text{array } (\text{mut}^? zt)}{C \vdash \text{array.new_fixed } x \ n : \text{unpack}(zt)^n \rightarrow (\text{ref } x)}$$

`array.new_elem $x \ y$`

The instruction `(array.new_elem $x \ y$)` is valid with the instruction type $\text{i32 } \text{i32} \rightarrow (\text{ref } x)$ if:

- The type $C.\text{types}[x]$ exists.
- The expansion of $C.\text{types}[x]$ is $(\text{array } (\text{mut}^? rt))$.
- The element segment $C.\text{elems}[y]$ exists.
- The element segment $C.\text{elems}[y]$ matches the reference type rt .

$$\frac{C.\text{types}[x] \approx \text{array } (\text{mut}^? rt) \quad C \vdash C.\text{elems}[y] \leq rt}{C \vdash \text{array.new_elem } x \ y : \text{i32 } \text{i32} \rightarrow (\text{ref } x)}$$

`array.new_data $x \ y$`

The instruction `(array.new_data $x \ y$)` is valid with the instruction type $\text{i32 } \text{i32} \rightarrow (\text{ref } x)$ if:

- The type $C.\text{types}[x]$ exists.
- The expansion of $C.\text{types}[x]$ is $(\text{array } (\text{mut}^? zt))$.
- The value type $\text{unpack}(zt)$ is of the form *numtype* or $\text{unpack}(zt)$ is of the form *vectype*.
- The data segment $C.\text{datas}[y]$ exists.

- The data segment $C.datas[y]$ is of the form ok .

$$\frac{C.types[x] \approx \text{array}(\text{mut}^? zt) \quad \text{unpack}(zt) = \text{numtype} \vee \text{unpack}(zt) = \text{vectype} \quad C.datas[y] = ok}{C \vdash \text{array.new_data } x \ y : i32 \ i32 \rightarrow (\text{ref } x)}$$

$\text{array.get_sx}^? \ x$

The instruction $(\text{array.get_sx}^? \ x)$ is valid with the instruction type $(\text{ref null } x) \ i32 \rightarrow t$ if:

- The type $C.types[x]$ exists.
- The expansion of $C.types[x]$ is $(\text{array}(\text{mut}^? zt))$.
- The signedness $sx^?$ is absent if and only if zt is a packed type.
- The value type t is $\text{unpack}(zt)$.

$$\frac{C.types[x] \approx \text{array}(\text{mut}^? zt) \quad sx^? = \epsilon \Leftrightarrow zt = \text{unpack}(zt)}{C \vdash \text{array.get_sx}^? \ x : (\text{ref null } x) \ i32 \rightarrow \text{unpack}(zt)}$$

$\text{array.set } x$

The instruction $(\text{array.set } x)$ is valid with the instruction type $(\text{ref null } x) \ i32 \ t \rightarrow \epsilon$ if:

- The type $C.types[x]$ exists.
- The expansion of $C.types[x]$ is $(\text{array}(\text{mut } zt))$.
- The value type t is $\text{unpack}(zt)$.

$$\frac{C.types[x] \approx \text{array}(\text{mut } zt)}{C \vdash \text{array.set } x : (\text{ref null } x) \ i32 \ \text{unpack}(zt) \rightarrow \epsilon}$$

array.len

The instruction array.len is valid with the instruction type $(\text{ref null array}) \rightarrow i32$.

$$\overline{C \vdash \text{array.len} : (\text{ref null array}) \rightarrow i32}$$

$\text{array.fill } x$

The instruction $(\text{array.fill } x)$ is valid with the instruction type $(\text{ref null } x) \ i32 \ t \ i32 \rightarrow \epsilon$ if:

- The type $C.types[x]$ exists.
- The expansion of $C.types[x]$ is $(\text{array}(\text{mut } zt))$.
- The value type t is $\text{unpack}(zt)$.

$$\frac{C.types[x] \approx \text{array}(\text{mut } zt)}{C \vdash \text{array.fill } x : (\text{ref null } x) \ i32 \ \text{unpack}(zt) \ i32 \rightarrow \epsilon}$$

$\text{array.copy } x \ y$

The instruction $(\text{array.copy } x_1 \ x_2)$ is valid with the instruction type $(\text{ref null } x_1) \ i32 \ (\text{ref null } x_2) \ i32 \ i32 \rightarrow \epsilon$ if:

- The type $C.types[x_1]$ exists.
- The expansion of $C.types[x_1]$ is $(\text{array}(\text{mut } zt_1))$.
- The type $C.types[x_2]$ exists.
- The expansion of $C.types[x_2]$ is $(\text{array}(\text{mut}^? zt_2))$.
- The storage type zt_2 matches the storage type zt_1 .

$$\frac{C.types[x_1] \approx \text{array}(\text{mut } zt_1) \quad C.types[x_2] \approx \text{array}(\text{mut}^? zt_2) \quad C \vdash zt_2 \leq zt_1}{C \vdash \text{array.copy } x_1 \ x_2 : (\text{ref null } x_1) \ i32 \ (\text{ref null } x_2) \ i32 \ i32 \rightarrow \epsilon}$$

`array.init_elem x y`

The instruction `(array.init_elem x y)` is valid with the instruction type $(\text{ref null } x) \text{ i32 i32 i32} \rightarrow \epsilon$ if:

- The type $C.\text{types}[x]$ exists.
- The expansion of $C.\text{types}[x]$ is $(\text{array } (\text{mut } zt))$.
- The element segment $C.\text{elems}[y]$ exists.
- The element segment $C.\text{elems}[y]$ matches the storage type zt .

$$\frac{C.\text{types}[x] \approx \text{array } (\text{mut } zt) \quad C \vdash C.\text{elems}[y] \leq zt}{C \vdash \text{array.init_elem } x \ y : (\text{ref null } x) \text{ i32 i32 i32} \rightarrow \epsilon}$$

`array.init_data x y`

The instruction `(array.init_data x y)` is valid with the instruction type $(\text{ref null } x) \text{ i32 i32 i32} \rightarrow \epsilon$ if:

- The type $C.\text{types}[x]$ exists.
- The expansion of $C.\text{types}[x]$ is $(\text{array } (\text{mut } zt))$.
- The value type $\text{unpack}(zt)$ is of the form *numtype* or $\text{unpack}(zt)$ is of the form *vectype*.
- The data segment $C.\text{datas}[y]$ exists.
- The data segment $C.\text{datas}[y]$ is of the form *ok*.

$$\frac{C.\text{types}[x] \approx \text{array } (\text{mut } zt) \quad \text{unpack}(zt) = \text{numtype} \vee \text{unpack}(zt) = \text{vectype} \quad C.\text{datas}[y] = \text{ok}}{C \vdash \text{array.init_data } x \ y : (\text{ref null } x) \text{ i32 i32 i32} \rightarrow \epsilon}$$

3.4.8 Scalar Reference Instructions

`ref.i31`

The instruction `ref.i31` is valid with the instruction type $\text{i32} \rightarrow (\text{ref } \text{i31})$.

$$\overline{C \vdash \text{ref.i31} : \text{i32} \rightarrow (\text{ref } \text{i31})}$$

`i31.get_sx`

The instruction `(i31.get_sx)` is valid with the instruction type $(\text{ref null } \text{i31}) \rightarrow \text{i32}$.

$$\overline{C \vdash \text{i31.get_sx} : (\text{ref null } \text{i31}) \rightarrow \text{i32}}$$

3.4.9 External Reference Instructions

`any.convert_extern`

The instruction `any.convert_extern` is valid with the instruction type $(\text{ref null}_1^? \text{ extern}) \rightarrow (\text{ref null}_2^? \text{ any})$ if:

- $\text{null}_1^?$ is of the form $\text{null}_2^?$.

$$\frac{\text{null}_1^? = \text{null}_2^?}{C \vdash \text{any.convert_extern} : (\text{ref null}_1^? \text{ extern}) \rightarrow (\text{ref null}_2^? \text{ any})}$$

`extern.convert_any`

The instruction `extern.convert_any` is valid with the instruction type $(\text{ref null}_1^? \text{ any}) \rightarrow (\text{ref null}_2^? \text{ extern})$ if:

- $\text{null}_1^?$ is of the form $\text{null}_2^?$.

$$\frac{\text{null}_1^? = \text{null}_2^?}{C \vdash \text{extern.convert_any} : (\text{ref null}_1^? \text{ any}) \rightarrow (\text{ref null}_2^? \text{ extern})}$$

3.4.10 Numeric Instructions

t.const c

The instruction $(nt.\text{const } c_{nt})$ is valid with the instruction type $\epsilon \rightarrow nt$.

$$\overline{C \vdash nt.\text{const } c_{nt} : \epsilon \rightarrow nt}$$

t.unop

The instruction $(nt.\text{unop}_{nt})$ is valid with the instruction type $nt \rightarrow nt$.

$$\overline{C \vdash nt.\text{unop}_{nt} : nt \rightarrow nt}$$

t.binop

The instruction $(nt.\text{binop}_{nt})$ is valid with the instruction type $nt \ nt \rightarrow nt$.

$$\overline{C \vdash nt.\text{binop}_{nt} : nt \ nt \rightarrow nt}$$

t.testop

The instruction $(nt.\text{testop}_{nt})$ is valid with the instruction type $nt \rightarrow i32$.

$$\overline{C \vdash nt.\text{testop}_{nt} : nt \rightarrow i32}$$

t.relop

The instruction $(nt.\text{relop}_{nt})$ is valid with the instruction type $nt \ nt \rightarrow i32$.

$$\overline{C \vdash nt.\text{relop}_{nt} : nt \ nt \rightarrow i32}$$

t₁.cvtop_t₂_sx?

The instruction $(nt_1.\text{cvtop_nt}_2)$ is valid with the instruction type $nt_2 \rightarrow nt_1$.

$$\overline{C \vdash nt_1.\text{cvtop_nt}_2 : nt_2 \rightarrow nt_1}$$

3.4.11 Vector Instructions

Vector instructions can have a prefix to describe the [shape](#) of the operand. Packed numeric types, [i8](#) and [i16](#), are not [value types](#). An auxiliary function maps such packed type shapes to value types:

$$\text{unpack}(i \times N) = \text{unpack}(i)$$

v128.const c

The instruction $(v128.\text{const } c)$ is valid with the instruction type $\epsilon \rightarrow v128$.

$$\overline{C \vdash v128.\text{const } c : \epsilon \rightarrow v128}$$

v128.vvunop

The instruction $(v128.\text{vvunop})$ is valid with the instruction type $v128 \rightarrow v128$.

$$\overline{C \vdash v128.\text{vvunop} : v128 \rightarrow v128}$$

v128.vbinop

The instruction (*v128.vbinop*) is valid with the instruction type $v128\ v128 \rightarrow v128$.

$$\overline{C \vdash v128.vbinop : v128\ v128 \rightarrow v128}$$

v128.vternop

The instruction (*v128.vternop*) is valid with the instruction type $v128\ v128\ v128 \rightarrow v128$.

$$\overline{C \vdash v128.vternop : v128\ v128\ v128 \rightarrow v128}$$

v128.vtestop

The instruction (*v128.vtestop*) is valid with the instruction type $v128 \rightarrow i32$.

$$\overline{C \vdash v128.vtestop : v128 \rightarrow i32}$$

shape.vunop

The instruction (*sh.vunop*) is valid with the instruction type $v128 \rightarrow v128$.

$$\overline{C \vdash sh.vunop : v128 \rightarrow v128}$$

shape.vbinop

The instruction (*sh.vbinop*) is valid with the instruction type $v128\ v128 \rightarrow v128$.

$$\overline{C \vdash sh.vbinop : v128\ v128 \rightarrow v128}$$

shape.vternop

The instruction (*sh.vternop*) is valid with the instruction type $v128\ v128\ v128 \rightarrow v128$.

$$\overline{C \vdash sh.vternop : v128\ v128\ v128 \rightarrow v128}$$

shape.vtestop

The instruction (*sh.vtestop*) is valid with the instruction type $v128 \rightarrow i32$.

$$\overline{C \vdash sh.vtestop : v128 \rightarrow i32}$$

shape.vrelop

The instruction (*sh.vrelop*) is valid with the instruction type $v128\ v128 \rightarrow v128$.

$$\overline{C \vdash sh.vrelop : v128\ v128 \rightarrow v128}$$

ishape.vshiftop

The instruction (*sh.vshiftop*) is valid with the instruction type $v128\ i32 \rightarrow v128$.

$$\overline{C \vdash sh.vshiftop : v128\ i32 \rightarrow v128}$$

ishape.bitmask

The instruction (*sh.bitmask*) is valid with the instruction type $v128 \rightarrow i32$.

$$\overline{C \vdash sh.bitmask : v128 \rightarrow i32}$$

i8x16.vswizzlop

The instruction (*sh.vswizzlop*) is valid with the instruction type $v_{128} \ v_{128} \rightarrow v_{128}$.

$$\overline{C \vdash sh.vswizzlop : v_{128} \ v_{128} \rightarrow v_{128}}$$

*i8x16.shuffle laneidx*¹⁶

The instruction (*sh.shuffle i**) is valid with the instruction type $v_{128} \ v_{128} \rightarrow v_{128}$ if:

- For all i in i^* :
 - The lane index i is less than $2 \cdot \dim(sh)$.

$$\frac{(i < 2 \cdot \dim(sh))^*}{C \vdash sh.shuffle \ i^* : v_{128} \ v_{128} \rightarrow v_{128}}$$

shape.splat

The instruction (*sh.splat*) is valid with the instruction type $numtype \rightarrow v_{128}$ if:

- The number type $numtype$ is $\text{unpack}(sh)$.

$$\overline{C \vdash sh.splat : \text{unpack}(sh) \rightarrow v_{128}}$$

shape.extract_lane_sx[?] laneidx

The instruction (*sh.extract_lane_sx[?] i*) is valid with the instruction type $v_{128} \rightarrow numtype$ if:

- The lane index i is less than $\dim(sh)$.
- The number type $numtype$ is $\text{unpack}(sh)$.

$$\frac{i < \dim(sh)}{C \vdash sh.extract_lane_sx^? \ i : v_{128} \rightarrow \text{unpack}(sh)}$$

shape.replace_lane laneidx

The instruction (*sh.replace_lane i*) is valid with the instruction type $v_{128} \ numtype \rightarrow v_{128}$ if:

- The lane index i is less than $\dim(sh)$.
- The number type $numtype$ is $\text{unpack}(sh)$.

$$\frac{i < \dim(sh)}{C \vdash sh.replace_lane \ i : v_{128} \ \text{unpack}(sh) \rightarrow v_{128}}$$

ishape₁.vextunop_ishape₂

The instruction (*sh₁.vextunop_sh₂*) is valid with the instruction type $v_{128} \rightarrow v_{128}$.

$$\overline{C \vdash sh_1.vextunop_sh_2 : v_{128} \rightarrow v_{128}}$$

ishape₁.vextbinop_ishape₂

The instruction (*sh₁.vextbinop_sh₂*) is valid with the instruction type $v_{128} \ v_{128} \rightarrow v_{128}$.

$$\overline{C \vdash sh_1.vextbinop_sh_2 : v_{128} \ v_{128} \rightarrow v_{128}}$$

ishape₁.vextternop_ishape₂

The instruction (*sh₁.vextternop_sh₂*) is valid with the instruction type $v_{128} \ v_{128} \ v_{128} \rightarrow v_{128}$.

$$\overline{C \vdash sh_1.vextternop_sh_2 : v_{128} \ v_{128} \ v_{128} \rightarrow v_{128}}$$

$ishape_1.narrow_ishape_2_sx$

The instruction $(sh_1.narrow_sh2_sx)$ is valid with the instruction type $v128\ v128 \rightarrow v128$.

$$\overline{C \vdash sh_1.narrow_sh2_sx : v128\ v128 \rightarrow v128}$$

$shape.vcvttop_half?_shape_sx?_zero?$

The instruction $(sh_1.vcvttop_sh2)$ is valid with the instruction type $v128 \rightarrow v128$.

$$\overline{C \vdash sh_1.vcvttop_sh2 : v128 \rightarrow v128}$$

3.4.12 Instruction Sequences

Typing of instruction sequences is defined recursively.

Empty Instruction Sequence: ϵ

The instruction sequence $instr^*$ is valid with the instruction type it if:

- Either:
 - The instruction sequence $instr^*$ is empty.
 - The instruction type it is of the form $\epsilon \rightarrow \epsilon$.
- Or:
 - The instruction sequence $instr^*$ is of the form $instr_1\ instr_2^*$.
 - The instruction type it is of the form $t_1^* \rightarrow_{x_1^*} t_2^*$.
 - The instruction $instr_1$ is valid with the instruction type $t_1^* \rightarrow_{x_1^*} t_2^*$.
 - For all x_1 in x_1^* :
 - * The local $C.locals[x_1]$ exists.
 - * The local $C.locals[x_1]$ is of the form $(init\ t)$.
 - Under the context C with the local types of x_1^* updated to $(set\ t)^*$, the instruction sequence $instr_2^*$ is valid with the instruction type $t_2^* \rightarrow_{x_2^*} t_3^*$.
- Or:
 - The instruction sequence $instr^*$ is valid with the instruction type it'' .
 - The instruction type it'' matches the instruction type it .
 - The instruction type it is valid.
- Or:
 - The instruction type it is of the form $t^*\ t_1^* \rightarrow_{x^*} t^*\ t_2^*$.
 - The instruction sequence $instr^*$ is valid with the instruction type $t_1^* \rightarrow_{x^*} t_2^*$.
 - The result type t^* is valid.

$$\begin{array}{c} \overline{C \vdash \epsilon : \epsilon \rightarrow \epsilon} \\ \\ \frac{C \vdash instr_1 : t_1^* \rightarrow_{x_1^*} t_2^* \quad (C.locals[x_1] = init\ t)^* \quad C[.local[x_1] = (set\ t)^*] \vdash instr_2^* : t_2^* \rightarrow_{x_2^*} t_3^*}{C \vdash instr_1\ instr_2^* : t_1^* \rightarrow_{x_1^*} t_2^* \rightarrow_{x_2^*} t_3^*} \\ \\ \frac{C \vdash instr^* : it \quad C \vdash it \leq it' \quad C \vdash it' : ok}{C \vdash instr^* : it'} \quad \frac{C \vdash instr^* : t_1^* \rightarrow_{x^*} t_2^* \quad C \vdash t^* : ok}{C \vdash instr^* : (t^*\ t_1^*) \rightarrow_{x^*} (t^*\ t_2^*)} \end{array}$$

Note

In combination with the previous rule, subsumption allows to compose instructions whose types would not directly fit otherwise. For example, consider the instruction sequence

$$(i32.const\ 1)\ (i32.const\ 2)\ (i32.add)$$

To type this sequence, its subsequence $(i32.const\ 2)\ (i32.add)$ needs to be valid with an intermediate type. But the direct type of $(i32.const\ 2)$ is $\epsilon \rightarrow i32$, not matching the two inputs expected by $i32.add$. The subsumption rule allows to weaken the type of $(const\ i32\ 2)$ to the supertype $i32 \rightarrow i32\ i32$, such that it can be composed with $i32.add$ and yields the intermediate type $i32 \rightarrow i32\ i32$ for the subsequence. That can in turn be composed with the first constant.

Furthermore, subsumption allows to drop init variables x^* from the instruction type in a context where they are not needed, for example, at the end of the body of a `block`.

3.4.13 Expressions

Expressions *expr* are classified by result types t^* .

The expression $instr^*$ is valid with the result type t^* if:

- The instruction sequence $instr^*$ is valid with the instruction type $\epsilon \rightarrow t^*$.

$$\frac{C \vdash instr^* : \epsilon \rightarrow_{\epsilon} t^*}{C \vdash instr^* : t^*}$$

Constant Expressions

In a *constant* expression, all instructions must be constant.

$instr^*$ is constant if:

- For all $instr$ in $instr^*$:
 - $instr$ is constant.

val is constant if:

- Either:
 - The value val is of the form $(nt.const\ c_{nt})$.
- Or:
 - The value val is of the form $(vt.const\ c_{vt})$.
- Or:
 - The value val is of the form $(ref.null\ ht)$.
- Or:
 - The value val is of the form $ref.i31$.
- Or:
 - The value val is of the form $(ref.func\ x)$.
- Or:
 - The value val is of the form $(struct.new\ x)$.
- Or:
 - The value val is of the form $(struct.new_default\ x)$.
- Or:

- The value *val* is of the form `(array.new x)`.
- Or:
 - The value *val* is of the form `(array.new_default x)`.
- Or:
 - The value *val* is of the form `(array.new_fixed x n)`.
- Or:
 - The value *val* is of the form `any.convert_extern`.
- Or:
 - The value *val* is of the form `extern.convert_any`.
- Or:
 - The value *val* is of the form `(global.get x)`.
 - The global `C.globals[x]` exists.
 - The global `C.globals[x]` is of the form (ϵt) .
- Or:
 - The value *val* is of the form `(iN.binop)`.
 - *iN* is contained in `[i32; i64]`.
 - *binop* is contained in `[add; sub; mul]`.

$$\begin{array}{c}
\frac{(C \vdash instr \text{ const})^*}{C \vdash instr^* \text{ const}} \\
\\
\frac{}{C \vdash (nt.\text{const } c_{nt}) \text{ const}} \quad \frac{}{C \vdash (vt.\text{const } c_{vt}) \text{ const}} \quad \frac{iN \in i32 \ i64 \quad binop \in \text{add sub mul}}{C \vdash (iN.binop) \text{ const}} \\
\\
\frac{}{C \vdash (\text{ref.null } ht) \text{ const}} \quad \frac{}{C \vdash (\text{ref.i31}) \text{ const}} \quad \frac{}{C \vdash (\text{ref.func } x) \text{ const}} \\
\\
\frac{}{C \vdash (\text{struct.new } x) \text{ const}} \quad \frac{}{C \vdash (\text{struct.new_default } x) \text{ const}} \\
\\
\frac{}{C \vdash (\text{array.new } x) \text{ const}} \quad \frac{}{C \vdash (\text{array.new_default } x) \text{ const}} \quad \frac{}{C \vdash (\text{array.new_fixed } x \ n) \text{ const}} \\
\\
\frac{}{C \vdash (\text{any.convert_extern}) \text{ const}} \quad \frac{}{C \vdash (\text{extern.convert_any}) \text{ const}} \\
\\
\frac{C.globals[x] = t}{C \vdash (\text{global.get } x) \text{ const}}
\end{array}$$

Note

Currently, constant expressions occurring in `globals` are further constrained in that contained `global.get` instructions are only allowed to refer to *imported* or *previously defined* globals. Constant expressions occurring in `tables` may only have `global.get` instructions that refer to *imported* globals. This is enforced in the [validation rule for modules](#) by constraining the context *C* accordingly.

The definition of constant expression may be extended in future versions of WebAssembly.

3.5 Modules

`Modules` are valid when all the components they contain are valid. To verify this, most definitions are themselves classified with a suitable type.

3.5.1 Types

The sequence of **types** defined in a module is validated incrementally, yielding a sequence of **defined types** representing them individually.

The **type definition** (**type rectype**) is **valid** with the defined type sequence dt^* if:

- The length of $C.types$ is equal to x .
- The defined type sequence dt^* is of the form $roll_x^*(rectype)$.
- Let C' be the same context as C , but with the defined type sequence dt^* appended to the field **types**.
- Under the context C' , the **recursive type rectype** is **valid** for the type index x .

$$\frac{x = |C.types| \quad dt^* = roll_x^*(rectype) \quad C \oplus \{types \ dt^*\} \vdash rectype : ok(x)}{C \vdash type \ rectype : dt^*}$$

The type definition sequence $type^*$ is **valid** with the defined type sequence $deftype^*$ if:

- Either:
 - The type definition sequence $type^*$ is empty.
 - The defined type sequence $deftype^*$ is empty.
- Or:
 - The type definition sequence $type^*$ is of the form $type_1 \ type'^*$.
 - The defined type sequence $deftype^*$ is of the form $dt_1^* \ dt^*$.
 - The type definition $type_1$ is **valid** with the defined type sequence dt_1^* .
 - Let C' be the same context as C , but with the defined type sequence dt_1^* appended to the field **types**.
 - Under the context C' , the type definition sequence $type'^*$ is **valid** with the defined type sequence dt^* .

$$\frac{C \vdash type_1 : dt_1^* \quad C \oplus \{types \ dt_1^*\} \vdash type^* : dt^*}{C \vdash type_1 \ type^* : dt_1^* \ dt^*}$$

3.5.2 Tags

Tags **tag** are classified by their **tag types**, which are **defined types** expanding to **function types**.

The **tag** (**tag tagtype**) is **valid** with the **tag type** $tagtype'$ if:

- The **tag type** $tagtype$ is **valid**.
- The **tag type** $tagtype'$ is $clos_C(tagtype)$.

$$\frac{C \vdash tagtype : ok}{C \vdash tag \ tagtype : clos_C(tagtype)}$$

3.5.3 Globals

Globals **global** are classified by **global types**.

The **global** (**global globaltype expr**) is **valid** with the **global type** $globaltype$ if:

- The **global type** $globaltype$ is **valid**.
- The **global type** $globaltype$ is of the form $(mut^? \ t)$.
- The **expression** $expr$ is **valid** with the value type t .
- $expr$ is constant.

$$\frac{C \vdash \text{globaltype} : \text{ok} \quad \text{globaltype} = \text{mut}^? t \quad C \vdash \text{expr} : t \text{ const}}{C \vdash \text{global } \text{globaltype } \text{expr} : \text{globaltype}}$$

Sequences of globals are handled incrementally, such that each definition has access to previous definitions.

The global sequence global^* is **valid** with the global type sequence globaltype^* if:

- Either:
 - The global sequence global^* is empty.
 - The global type sequence globaltype^* is empty.
- Or:
 - The global sequence global^* is of the form $\text{global}_1 \text{global}'^*$.
 - The global type sequence globaltype^* is of the form $gt_1 gt^*$.
 - The **global** global_1 is **valid** with the **global type** gt_1 .
 - Let C' be the same context as C , but with the global type sequence gt_1 appended to the field **globals**.
 - Under the context C' , the global sequence global'^* is **valid** with the global type sequence gt^* .

$$\frac{}{C \vdash \epsilon : \epsilon} \quad \frac{C \vdash \text{global}_1 : gt_1 \quad C \oplus \{\text{globals } gt_1\} \vdash \text{global}'^* : gt^*}{C \vdash \text{global}_1 \text{global}'^* : gt_1 gt^*}$$

3.5.4 Memories

Memories *mem* are classified by **memory types**.

The **memory** (memory *memtype*) is **valid** with the **memory type** *memtype* if:

- The **memory type** *memtype* is **valid**.

$$\frac{C \vdash \text{memtype} : \text{ok}}{C \vdash \text{memory } \text{memtype} : \text{memtype}}$$

3.5.5 Tables

Tables *table* are classified by **table types**.

The **table** (table *tabletype expr*) is **valid** with the **table type** *tabletype* if:

- The **table type** *tabletype* is **valid**.
- The **table type** *tabletype* is of the form $(\text{at } \text{lim } rt)$.
- The **expression** *expr* is **valid** with the **value type** *rt*.
- *expr* is **constant**.

$$\frac{C \vdash \text{tabletype} : \text{ok} \quad \text{tabletype} = \text{at } \text{lim } rt \quad C \vdash \text{expr} : rt \text{ const}}{C \vdash \text{table } \text{tabletype } \text{expr} : \text{tabletype}}$$

3.5.6 Functions

Functions *func* are classified by **defined types** that expand to **function types** of the form $\text{func } t_1^* \rightarrow t_2^*$.

The **function** (**func** *x local*^{*} *expr*) is **valid** with the type $C.\text{types}[x]$ if:

- The type $C.\text{types}[x]$ exists.
- The **expansion** of $C.\text{types}[x]$ is $(\text{func } t_1^* \rightarrow t_2^*)$.
- For all *local* in *local*^{*}:
 - The **local** *local* is **valid** with the **local type** *lt*.

- lt^* is the concatenation of all such lt .
- Under the context C with the field **locals** appended by $(\text{set } t_1)^* lt^*$ and the field **labels** appended by t_2^* and the field **return** appended by t_2^* , the expression $expr$ is valid with the result type t_2^* .

$$\frac{C.\text{types}[x] \approx \text{func } t_1^* \rightarrow t_2^* \quad (C \vdash \text{local} : lt)^* \quad C \oplus \{\text{locals } (\text{set } t_1)^* lt^*, \text{labels } (t_2^*), \text{return } (t_2^*)\} \vdash expr : t_2^*}{C \vdash \text{func } x \text{ local}^* expr : C.\text{types}[x]}$$

3.5.7 Locals

Locals *local* are classified with **local types**.

The **local** ($\text{local } t$) is valid with the **local type** ($\text{init } t$) if:

- Either:
 - The **initialization status** *init* is of the form **set**.
 - A **default value** for t is defined.
- Or:
 - The **initialization status** *init* is of the form **unset**.
 - A **default value** for t is not defined.

$$\frac{\text{default}_t \neq \epsilon}{C \vdash \text{local } t : \text{set } t} \quad \frac{\text{default}_t = \epsilon}{C \vdash \text{local } t : \text{unset } t}$$

Note

For cases where both rules are applicable, the former yields the more permissable type.

3.5.8 Data Segments

Data segments *data* are classified by the singleton **data type**, which merely expresses well-formedness.

The **memory segment** ($\text{data } b^* \text{ datamode}$) is valid if:

- The **data mode** *datamode* is valid.

$$\frac{C \vdash \text{datamode} : \text{ok}}{C \vdash \text{data } b^* \text{ datamode} : \text{ok}}$$

The **data mode** *datamode* is valid if:

- Either:
 - The **data mode** *datamode* is of the form $(\text{active } x \text{ expr})$.
 - The **memory** $C.\text{mems}[x]$ exists.
 - The **memory** $C.\text{mems}[x]$ is of the form $(\text{at } \text{lim} \text{ page})$.
 - The expression $expr$ is valid with the **value type** at .
 - $expr$ is constant.

- Or:

- The **data mode** *datamode* is of the form **passive**.

$$\frac{C.\text{mems}[x] = \text{at } \text{lim} \text{ page} \quad C \vdash expr : \text{at } \text{const}}{C \vdash \text{active } x \text{ expr} : \text{ok}} \quad \frac{}{C \vdash \text{passive} : \text{ok}}$$

3.5.9 Element Segments

Element segments *elem* are classified by their element type.

The table segment (*elem elemtype expr* elemmode*) is valid with the element type *elemtype* if:

- The reference type *elemtype* is valid.
- For all *expr* in *expr**:
 - The expression *expr* is valid with the value type *elemtype*.
 - *expr* is constant.
- The element mode *elemmode* is valid with the element type *elemtype*.

$$\frac{C \vdash \text{elemtype} : \text{ok} \quad (C \vdash \text{expr} : \text{elemtype const})^* \quad C \vdash \text{elemmode} : \text{elemtype}}{C \vdash \text{elem elemtype expr* elemmode} : \text{elemtype}}$$

The element mode *elemmode* is valid with the element type *rt* if:

- Either:
 - The element mode *elemmode* is of the form (active *x expr*).
 - The table *C.tables[x]* exists.
 - The table *C.tables[x]* is of the form (at *lim rt'*).
 - The reference type *rt* matches the reference type *rt'*.
 - The expression *expr* is valid with the value type *at*.
 - *expr* is constant.
- Or:
 - The element mode *elemmode* is of the form passive.
- Or:
 - The element mode *elemmode* is of the form declare.

$$\frac{C.\text{tables}[x] = \text{at lim } rt' \quad C \vdash rt \leq rt' \quad C \vdash \text{expr} : \text{at const}}{C \vdash \text{active } x \text{ expr} : rt} \quad \frac{}{C \vdash \text{passive} : rt} \quad \frac{}{C \vdash \text{declare} : rt}$$

3.5.10 Start Function

The start function (start *x*) is valid if:

- The function *C.funcs[x]* exists.
- The expansion of *C.funcs[x]* is (func \rightarrow).

$$\frac{C.\text{funcs}[x] \approx \text{func } \epsilon \rightarrow \epsilon}{C \vdash \text{start } x : \text{ok}}$$

3.5.11 Imports

Imports *import* are classified by external types.

The import (import *name₁ name₂ xt*) is valid with the external type *externtype* if:

- The external type *xt* is valid.
- The external type *externtype* is *clos_C(xt)*.

$$\frac{C \vdash xt : \text{ok}}{C \vdash \text{import name}_1 \text{ name}_2 xt : \text{clos}_C(xt)}$$

3.5.12 Exports

Exports *export* are classified by their external type.

The export (export *name externidx*) is valid with the name *name* and the external type *xt* if:

- The external index *externidx* is valid with the external type *xt*.

$$\frac{C \vdash \text{externidx} : xt}{C \vdash \text{export name externidx} : \text{name xt}}$$

tag *x*

The external index (tag *x*) is valid with the external type (tag *jt*) if:

- The tag *C.tags[x]* exists.
- The tag *C.tags[x]* is of the form *jt*.

$$\frac{C.\text{tags}[x] = jt}{C \vdash \text{tag } x : \text{tag } jt}$$

global *x*

The external index (global *x*) is valid with the external type (global *gt*) if:

- The global *C.globals[x]* exists.
- The global *C.globals[x]* is of the form *gt*.

$$\frac{C.\text{globals}[x] = gt}{C \vdash \text{global } x : \text{global } gt}$$

memory *x*

The external index (memory *x*) is valid with the external type (mem *mt*) if:

- The memory *C.mems[x]* exists.
- The memory *C.mems[x]* is of the form *mt*.

$$\frac{C.\text{mems}[x] = mt}{C \vdash \text{memory } x : \text{mem } mt}$$

table *x*

The external index (table *x*) is valid with the external type (table *tt*) if:

- The table *C.tables[x]* exists.
- The table *C.tables[x]* is of the form *tt*.

$$\frac{C.\text{tables}[x] = tt}{C \vdash \text{table } x : \text{table } tt}$$

func *x*

The external index (func *x*) is valid with the external type (func *dt*) if:

- The function *C.funcs[x]* exists.
- The function *C.funcs[x]* is of the form *dt*.

$$\frac{C.\text{funcs}[x] = dt}{C \vdash \text{func } x : \text{func } dt}$$

3.5.13 Modules

Modules are classified by their mapping from the [external types](#) of their [imports](#) to those of their [exports](#).

A module is entirely *closed*, that is, its components can only refer to definitions that appear in the module itself. Consequently, no initial [context](#) is required. Instead, the [context](#) C for validation of the module's content is constructed from the definitions in the module.

The [module](#) ($\text{module } type^* \text{ import}^* \text{ tag}^* \text{ global}^* \text{ mem}^* \text{ table}^* \text{ func}^* \text{ data}^* \text{ elem}^* \text{ start}^? \text{ export}^*$) is [valid](#) with the [module type](#) $moduletype$ if:

- Under the context $\{\text{return } \epsilon\}$, the type definition sequence $type^*$ is [valid](#) with the defined type sequence dt'^* .
- For all $import$ in $import^*$:
 - Under the context $\{\text{types } dt'^*, \text{return } \epsilon\}$, the [import](#) $import$ is [valid](#) with the [external type](#) xt_i .
- xt_i^* is the concatenation of all such xt_i .
- For all tag in tag^* :
 - Under the context C' , the [tag](#) tag is [valid](#) with the [tag type](#) jt .
- jt^* is the concatenation of all such jt .
- Under the context C' , the global sequence $global^*$ is [valid](#) with the global type sequence gt^* .
- For all mem in mem^* :
 - Under the context C' , the [memory](#) mem is [valid](#) with the [memory type](#) mt .
- mt^* is the concatenation of all such mt .
- For all $table$ in $table^*$:
 - Under the context C' , the [table](#) $table$ is [valid](#) with the [table type](#) tt .
- tt^* is the concatenation of all such tt .
- For all $func$ in $func^*$:
 - The [function](#) $func$ is [valid](#) with the [defined type](#) dt .
- dt^* is the concatenation of all such dt .
- For all $data$ in $data^*$:
 - The [memory segment](#) $data$ is [valid](#).
- ok^* is the concatenation of all such ok .
- For all $elem$ in $elem^*$:
 - The [table segment](#) $elem$ is [valid](#) with the [element type](#) rt .
- rt^* is the concatenation of all such rt .
- If $start$ is defined, then:
 - The [start function](#) $start$ is [valid](#).
- For all $export$ in $export^*$:
 - The [export](#) $export$ is [valid](#) with the [name](#) nm and the [external type](#) xt_e .
- nm^* is the concatenation of all such nm .
- xt_e^* is the concatenation of all such xt_e .
- nm^* disjoint is true.
- The [context](#) C' is of the form C' with the field [tags](#) appended by jt_i^* jt^* and the field [globals](#) appended by gt^* and the field [mems](#) appended by mt_i^* mt^* and the field [tables](#) appended by tt_i^* tt^* and the field [datas](#) appended by ok^* and the field [elems](#) appended by rt^* .
- The [context](#) C' is of the form $\{\text{types } dt'^*, \text{globals } gt_i^*, \text{funcs } dt_i^*, \text{return } \epsilon, \text{refs } x^*\}$.

- The function index sequence x^* is of the form $\text{funcidx}(\text{global}^* \text{ mem}^* \text{ table}^* \text{ elem}^*)$.
- The tag type sequence jt_i^* is of the form $\text{tags}(xt_i^*)$.
- The global type sequence gt_i^* is of the form $\text{globals}(xt_i^*)$.
- The memory type sequence mt_i^* is of the form $\text{mems}(xt_i^*)$.
- The table type sequence tt_i^* is of the form $\text{tables}(xt_i^*)$.
- The defined type sequence dt_i^* is of the form $\text{funcs}(xt_i^*)$.
- The module type moduletype is $\text{clos}_C(xt_i^* \rightarrow xt_e^*)$.

$$\begin{array}{c}
\{\} \vdash \text{type}^* : dt'^* \quad (\{\text{types } dt'^*\} \vdash \text{import} : xt_i^*)^* \\
(C' \vdash \text{tag} : jt)^* \quad C' \vdash \text{global}^* : gt^* \quad (C' \vdash \text{mem} : mt)^* \quad (C' \vdash \text{table} : tt)^* \quad (C \vdash \text{func} : dt)^* \\
(C \vdash \text{data} : ok)^* \quad (C \vdash \text{elem} : rt)^* \quad (C \vdash \text{start} : ok)^? \quad (C \vdash \text{export} : nm \text{ } xt_e^*)^* \quad nm^* \text{ disjoint} \\
C = C' \oplus \{\text{tags } jt_i^* \text{ } jt^*, \text{ globals } gt^*, \text{ mems } mt_i^* \text{ } mt^*, \text{ tables } tt_i^* \text{ } tt^*, \text{ datas } ok^*, \text{ elems } rt^*\} \\
C' = \{\text{types } dt'^*, \text{ globals } gt_i^*, \text{ funcs } dt_i^* \text{ } dt^*, \text{ refs } x^*\} \quad x^* = \text{funcidx}(\text{global}^* \text{ mem}^* \text{ table}^* \text{ elem}^*) \\
jt_i^* = \text{tags}(xt_i^*) \quad gt_i^* = \text{globals}(xt_i^*) \quad mt_i^* = \text{mems}(xt_i^*) \quad tt_i^* = \text{tables}(xt_i^*) \quad dt_i^* = \text{funcs}(xt_i^*) \\
\hline
\vdash \text{module type}^* \text{ import}^* \text{ tag}^* \text{ global}^* \text{ mem}^* \text{ table}^* \text{ func}^* \text{ data}^* \text{ elem}^* \text{ start}^? \text{ export}^* : \text{clos}_C(xt_i^* \rightarrow xt_e^*)
\end{array}$$

Note

All functions in a module are mutually recursive. Consequently, the definition of the **context** C in this rule is recursive: it depends on the outcome of validation of the function, table, memory, and global definitions contained in the module, which itself depends on C . However, this recursion is just a specification device. All types needed to construct C can easily be determined from a simple pre-pass over the module that does not perform any actual validation.

Globals, however, are not recursive but evaluated sequentially, such that each **constant expressions** only has access to imported or previously defined globals.

4.1 Conventions

WebAssembly code is *executed* when *instantiating* a module or *invoking* an *exported* function on the resulting module *instance*.

Execution behavior is defined in terms of an *abstract machine* that models the *program state*. It includes a *stack*, which records operand values and control constructs, and an abstract *store* containing global state.

For each instruction, there is a rule that specifies the effect of its execution on the program state. Furthermore, there are rules describing the instantiation of a module. As with *validation*, all rules are given in two *equivalent* forms:

1. In *prose*, describing the execution in intuitive form.
2. In *formal notation*, describing the rule in mathematical form.¹⁸

Note

As with validation, the prose and formal rules are equivalent, so that understanding of the formal notation is *not* required to read this specification. The formalism offers a more concise description in notation that is used widely in programming languages semantics and is readily amenable to mathematical proof.

4.1.1 Prose Notation

Execution is specified by stylised, step-wise rules for each *instruction* of the *abstract syntax*. The following conventions are adopted in stating these rules.

- The execution rules implicitly assume a given *store* *s*.
- The execution rules also assume the presence of an implicit *stack* that is modified by *pushing* or *popping* *values*, *labels*, and *frames*.
- Certain rules require the stack to contain at least one frame. The most recent frame is referred to as the *current* frame.

¹⁸ The semantics is derived from the following article: Andreas Haas, Andreas Rossberg, Derek Schuff, Ben Titzer, Dan Gohman, Luke Wagner, Alon Zakai, JF Bastien, Michael Holman. *Bringing the Web up to Speed with WebAssembly*¹⁹. Proceedings of the 38th ACM SIGPLAN Conference on Programming Language Design and Implementation (PLDI 2017). ACM 2017.

¹⁹ <https://dl.acm.org/citation.cfm?doid=3062341.3062363>

- Both the store and the current frame are mutated by *replacing* some of their components. Such replacement is assumed to apply globally.
- The execution of an instruction may *trap*, in which case the entire computation is aborted and no further modifications to the store are performed by it. (Other computations can still be initiated afterwards.)
- The execution of an instruction may also end in a *jump* to a designated target, which defines the next instruction to execute.
- Execution can *enter* and *exit* [instruction sequences](#) that form [blocks](#).
- [Instruction sequences](#) are implicitly executed in order, unless a trap, jump, or exception occurs.
- In various places the rules contain *assertions* expressing crucial invariants about the program state.

4.1.2 Formal Notation

Note

This section gives a brief explanation of the notation for specifying execution formally. For the interested reader, a more thorough introduction can be found in respective text books.²⁰

The formal execution rules use a standard approach for specifying operational semantics, rendering them into *reduction rules*. Every rule has the following general form:

$$configuration \hookrightarrow configuration$$

A *configuration* is a syntactic description of a program state. Each rule specifies one *step* of execution. As long as there is at most one reduction rule applicable to a given configuration, reduction – and thereby execution – is *deterministic*. WebAssembly has only very few exceptions to this, which are noted explicitly in this specification.

For WebAssembly, a configuration typically is a tuple $(s; f; instr^*)$ consisting of the current [store](#) s , the [call frame](#) f of the current function, and the sequence of [instructions](#) that is to be executed. (A more precise definition is given [later](#).)

To avoid unnecessary clutter, the store s and the frame f are often combined into a *state* z , which is a pair $(s; f)$. Moreover, z is omitted from reduction rules that do not touch them.

There is no separate representation of the [stack](#). Instead, it is conveniently represented as part of the configuration's instruction sequence. In particular, [values](#) are defined to coincide with `const` and `ref` instructions, and a sequence of such instructions can be interpreted as an operand “stack” that grows to the right.

Note

For example, the [reduction rule](#) for the `i32.add` instruction can be given as follows:

$$(i32.const\ n_1)\ (i32.const\ n_2)\ (i32.add) \hookrightarrow (i32.const\ (n_1 + n_2) \bmod 2^{32})$$

Per this rule, two `const` instructions and the `add` instruction itself are removed from the instruction stream and replaced with one new `const` instruction. This can be interpreted as popping two values off the stack and pushing the result.

When no result is produced, an instruction reduces to the empty sequence:

$$nop \hookrightarrow \epsilon$$

[Labels](#) and [frames](#) are similarly [defined](#) to be part of an instruction sequence.

²⁰ For example: Benjamin Pierce. [Types and Programming Languages](#)²¹. The MIT Press 2002

²¹ <https://www.cis.upenn.edu/~bcpierce/tapl/>

The order of reduction is determined by the details of the reduction rules. Usually, the left-most instruction that is not a constant will be the subject of the next reduction *step*.

Reduction *terminates* when no more reduction rules are applicable. [Soundness](#) of the WebAssembly type system guarantees that this is only the case when the original instruction sequence has either been reduced to a sequence of [value](#) instructions, which can be interpreted as the [values](#) of the resulting operand stack, or if an [exception](#) or [trap](#) occurred.

Note

For example, the following instruction sequence,

$$(f64.const\ q_1)\ (f64.const\ q_2)\ (f64.neg)\ (f64.const\ q_3)\ (f64.add)\ (f64.mul)$$

terminates after three steps:

$$\begin{aligned} \hookrightarrow & \ (f64.const\ q_1)\ (f64.const\ q_4)\ (f64.const\ q_3)\ (f64.add)\ (f64.mul) \\ \hookrightarrow & \ (f64.const\ q_1)\ (f64.const\ q_5)\ (f64.mul) \\ \hookrightarrow & \ (f64.const\ q_6) \end{aligned}$$

where $q_4 = -q_2$ and $q_5 = -q_2 + q_3$ and $q_6 = q_1 \cdot (-q_2 + q_3)$.

4.2 Runtime Structure

[Store](#), [stack](#), and other *runtime structure* forming the WebAssembly abstract machine, such as [values](#) or [module instances](#), are made precise in terms of additional auxiliary syntax.

4.2.1 Values

WebAssembly computations manipulate *values* of either the four basic [number types](#), i.e., [integers](#) and [floating-point data](#) of 32 or 64 bit width each, or [vectors](#) of 128 bit width, or of [reference type](#).

In most places of the semantics, values of different types can occur. In order to avoid ambiguities, values are therefore represented with an abstract syntax that makes their type explicit. It is convenient to reuse the same notation as for the [const instructions](#) and [ref.null](#) producing them.

References other than null are represented with additional [administrative instructions](#). They either are *scalar references*, containing a 31-bit [integer](#), *structure references*, pointing to a specific [structure address](#), *array references*, pointing to a specific [array address](#), *function references*, pointing to a specific [function address](#), *exception references*, pointing to a specific [exception address](#), or *host references* pointing to an uninterpreted form of [host address](#) defined by the [embedder](#). Any of the aforementioned references can furthermore be wrapped up as an *external reference*.

$$\begin{aligned} val &::= num \mid vec \mid ref \\ num &::= numtype.const\ num_{numtype} \\ vec &::= vectype.const\ vec_{vectype} \\ ref &::= addrref \\ &\quad \mid ref.null\ heapttype \\ addrref &::= ref.i31\ u31 \\ &\quad \mid ref.struct\ structaddr \\ &\quad \mid ref.array\ arrayaddr \\ &\quad \mid ref.func\ funcaddr \\ &\quad \mid ref.exn\ exnaddr \\ &\quad \mid ref.host\ hostaddr \\ &\quad \mid ref.extern\ addrref \end{aligned}$$

Note

Future versions of WebAssembly may add additional forms of values.

Value types can have an associated *default value*; it is the respective value 0 for **number types**, 0 for **vector types**, and null for nullable **reference types**. For other references, no default value is defined, default_t hence is an optional value $\text{val}^?$.

$$\begin{aligned} \text{default}_{iN} &= (iN.\text{const } 0) \\ \text{default}_{fN} &= (fN.\text{const } +0) \\ \text{default}_{vN} &= (vN.\text{const } 0) \\ \text{default}_{\text{ref null } ht} &= (\text{ref.null } ht) \\ \text{default}_{\text{ref } ht} &= \epsilon \end{aligned}$$

Convention

- The meta variable r ranges over reference values where clear from context.

4.2.2 Results

A *result* is the outcome of a computation. It is either a sequence of **values**, a thrown **exception**, or a **trap**.

$$\text{result} ::= \text{val}^* \mid (\text{ref.exn } \text{exnaddr}) \text{ throw_ref} \mid \text{trap}$$

4.2.3 Store

The *store* represents all global state that can be manipulated by WebAssembly programs. It consists of the runtime representation of all *instances* of **functions**, **tables**, **memories**, **globals**, **tags**, **element segments**, **data segments**, and **structures**, **arrays** or **exceptions** that have been **allocated** during the life time of the abstract machine.

It is an invariant of the semantics that no element or data instance is **addressed** from anywhere else but the owning module instances.

Syntactically, the store is defined as a **record** listing the existing instances of each category:

$$\text{store} ::= \{ \text{tags } \text{taginst}^* \\ \text{globals } \text{globalinst}^* \\ \text{mems } \text{meminst}^* \\ \text{tables } \text{tableinst}^* \\ \text{funcs } \text{funcinst}^* \\ \text{datas } \text{datainst}^* \\ \text{elems } \text{eleminst}^* \\ \text{structs } \text{structinst}^* \\ \text{arrays } \text{arrayinst}^* \\ \text{exns } \text{exninst}^* \}$$

Note

In practice, implementations may apply techniques like garbage collection or reference counting to remove objects from the store that are no longer referenced. However, such techniques are not semantically observable, and hence outside the scope of this specification.

Convention

- The meta variable s ranges over stores where clear from context.

4.2.4 Addresses

Function instances, table instances, memory instances, global instances, tag instances, element instances, data instances and structure, array or exception instances in the store are referenced with abstract *addresses*. These are simply indices into the respective store component. In addition, an *embedder* may supply an uninterpreted set of *host addresses*.

$$\begin{aligned}
 \text{addr} &::= 0 \mid 1 \mid 2 \mid \dots \\
 \text{funcaddr} &::= \text{addr} \\
 \text{tableaddr} &::= \text{addr} \\
 \text{memaddr} &::= \text{addr} \\
 \text{globaladdr} &::= \text{addr} \\
 \text{tagaddr} &::= \text{addr} \\
 \text{elemaddr} &::= \text{addr} \\
 \text{dataaddr} &::= \text{addr} \\
 \text{structaddr} &::= \text{addr} \\
 \text{arrayaddr} &::= \text{addr} \\
 \text{hostaddr} &::= \text{addr}
 \end{aligned}$$

An *embedder* may assign identity to *exported* store objects corresponding to their addresses, even where this identity is not observable from within WebAssembly code itself (such as for *function instances* or immutable *globals*).

Note

Addresses are *dynamic*, globally unique references to runtime objects, in contrast to *indices*, which are *static*, module-local references to their original definitions. A *memory address* *memaddr* denotes the abstract address of a memory *instance* in the store, not an offset *inside* a memory instance.

There is no specific limit on the number of allocations of store objects, hence logical addresses can be arbitrarily large natural numbers.

Conventions

- The notation $\text{addr}(A)$ denotes the set of addresses from address space *addr* occurring free in *A*. We sometimes reinterpret this set as the *list* of its elements, without assuming any particular order.

4.2.5 External Addresses

An *external address* is the runtime *address* of an entity that can be imported or exported. It is an *address* denoting either a *function instance*, *global instance*, *table instance*, *memory instance*, or *tag instance* in the shared *store*.

$$\text{externaddr} ::= \text{tag } \text{tagaddr} \mid \text{global } \text{globaladdr} \mid \text{mem } \text{memaddr} \mid \text{table } \text{tableaddr} \mid \text{func } \text{funcaddr}$$

4.2.6 Module Instances

A *module instance* is the runtime representation of a *module*. It is created by *instantiating* a module, and collects runtime representations of all entities that are imported, defined, or exported by the module.

$$\begin{aligned}
 \text{moduleinst} &::= \{ \text{types } \text{deftype}^* \\
 &\quad \text{tags } \text{tagaddr}^* \\
 &\quad \text{globals } \text{globaladdr}^* \\
 &\quad \text{mems } \text{memaddr}^* \\
 &\quad \text{tables } \text{tableaddr}^* \\
 &\quad \text{funcs } \text{funcaddr}^* \\
 &\quad \text{datas } \text{dataaddr}^* \\
 &\quad \text{elems } \text{elemaddr}^* \\
 &\quad \text{exports } \text{exportinst}^* \}
 \end{aligned}$$

Each component references runtime instances corresponding to respective declarations from the original module – whether imported or defined – in the order of their static [indices](#). [Function instances](#), [table instances](#), [memory instances](#), [global instances](#), and [tag instances](#) are denoted by their respective [addresses](#) in the [store](#).

It is an invariant of the semantics that all [export instances](#) in a given module instance have different [names](#).

Note

All record fields except exports are to be considered *private* components of a module instance. They are not accessible to other modules, only to function instances originating from the same module.

4.2.7 Function Instances

A *function instance* is the runtime representation of a [function](#). It effectively is a *closure* of the original function over the runtime [module instance](#) of its originating [module](#). The module instance is used to resolve references to other definitions during execution of the function.

$$\begin{aligned} \text{funcinst} &::= \{\text{type } \text{deftype}, \text{module } \text{moduleinst}, \text{code } \text{code}\} \\ \text{code} &::= \text{func} \mid \text{hostfunc} \end{aligned}$$

A *host function* is a function expressed outside WebAssembly but passed to a [module](#) as an [import](#). The definition and behavior of host functions are outside the scope of this specification. For the purpose of this specification, it is assumed that when [invoked](#), a host function behaves non-deterministically, but within certain [constraints](#) that ensure the integrity of the runtime.

Note

Function instances are immutable, and their identity is not observable by WebAssembly code. However, an [embedder](#) might provide implicit or explicit means for distinguishing their [addresses](#).

4.2.8 Table Instances

A *table instance* is the runtime representation of a [table](#). It records its [type](#) and holds a sequence of [reference values](#).

$$\text{tableinst} ::= \{\text{type } \text{tabletype}, \text{elem } \text{ref}^*\}$$

Table elements can be mutated through [table instructions](#), the execution of an active [element segment](#), or by external means provided by the [embedder](#).

It is an invariant of the semantics that all table elements have a type [matching](#) the element type of [tabletype](#). It also is an invariant that the length of the element sequence never exceeds the maximum size of [tabletype](#).

4.2.9 Memory Instances

A *memory instance* is the runtime representation of a linear [memory](#). It records its [type](#) and holds a sequence of bytes.

$$\text{meminst} ::= \{\text{type } \text{memtype}, \text{bytes } \text{byte}^*\}$$

The length of the sequence always is a multiple of the WebAssembly *page size*, which is defined to be the constant 65536 – abbreviated 64 Ki.

A memory's bytes can be mutated through [memory instructions](#), the execution of an active [data segment](#), or by external means provided by the [embedder](#).

It is an invariant of the semantics that the length of the byte sequence, divided by page size, never exceeds the maximum size of [memtype](#).

4.2.10 Global Instances

A *global instance* is the runtime representation of a [global variable](#). It records its [type](#) and holds an individual [value](#).

$$globalinst ::= \{type\ globaltype, value\ val\}$$

The value of mutable globals can be mutated through [variable instructions](#) or by external means provided by the embedder.

It is an invariant of the semantics that the value has a type [matching](#) the [value type](#) of *globaltype*.

4.2.11 Tag Instances

A *tag instance* is the runtime representation of a [tag definition](#). It records the [defined type](#) of the tag.

$$taginst ::= \{type\ tagtype\}$$

4.2.12 Element Instances

An *element instance* is the runtime representation of an [element segment](#). It holds a list of references and its [type](#).

$$eleminst ::= \{type\ elemtype, elem\ ref^*\}$$

It is an invariant of the semantics that all elements of a segment have a type [matching](#) *elemtype*.

4.2.13 Data Instances

An *data instance* is the runtime representation of a [data segment](#). It holds a list of [bytes](#).

$$datainst ::= \{bytes\ byte^*\}$$

4.2.14 Export Instances

An *export instance* is the runtime representation of an [export](#). It defines the export's [name](#) and the associated [external address](#).

$$exportinst ::= \{name\ name, addr\ externaddr\}$$

Conventions

The following auxiliary functions are assumed on sequences of external addresses. They extract addresses of a specific kind in an order-preserving fashion:

- `funcs(xa*)` extracts all [function addresses](#) from *xa*^{*},
- `tables(xa*)` extracts all [table addresses](#) from *xa*^{*},
- `mems(xa*)` extracts all [memory addresses](#) from *xa*^{*},
- `globals(xa*)` extracts all [global addresses](#) from *xa*^{*},
- `tags(xa*)` extracts all [tag addresses](#) from *xa*^{*}.

4.2.15 Aggregate Instances

A *structure instance* is the runtime representation of a heap object allocated from a [structure type](#). Likewise, an *array instance* is the runtime representation of a heap object allocated from an [array type](#). Both record their respective [defined type](#) and hold a list of the values of their *fields*.

$$\begin{aligned} structinst &::= \{type\ deftype, fields\ fieldval^*\} \\ arrayinst &::= \{type\ deftype, fields\ fieldval^*\} \\ fieldval &::= val \mid packval \\ packval &::= packtype.pack\ iN \end{aligned}$$

Conventions

- Conversion of a regular **value** to a **field value** is defined as follows:

$$\begin{aligned} \text{pack}_{\text{valtype}}(\text{val}) &= \text{val} \\ \text{pack}_{\text{packtype}}(\text{i32.const } i) &= \text{packtype.pack wrap}_{32,|\text{packtype}|}(i) \end{aligned}$$

- The inverse conversion of a **field value** to a regular **value** is defined as follows:

$$\begin{aligned} \text{unpack}_{\text{valtype}}^{\epsilon}(\text{val}) &= \text{val} \\ \text{unpack}_{\text{packtype}}^{sx}(\text{packtype.pack } i) &= \text{i32.const extend}_{|\text{packtype}|,32}^{sx}(i) \end{aligned}$$

4.2.16 Exception Instances

An *exception instance* is the runtime representation of an **exception** produced by a throw instruction. It holds the **address** of the respective **tag** and the argument **values**.

$$\text{exninst} ::= \{\text{tag } \text{tagaddr}, \text{fields } \text{val}^*\}$$

4.2.17 Stack

Besides the **store**, most **instructions** interact with an implicit *stack*. The stack contains the two kinds of entries:

- *Values*: the *operands* of instructions.
- *Control Frames*: currently active control flow structures.

The latter can in turn be one of the following:

- *Labels*: active **structured control instructions** that can be targeted by branches.
- *(Call) Frames*: the *activation records* of active **function** calls.
- *Handlers*: active exception handlers.

Note

Where clear from context, *call frame* is abbreviated to just *frame*.

All these entries can occur on the stack in any order during the execution of a program. Stack entries are described by abstract syntax as follows.

Note

It is possible to model the WebAssembly semantics using separate stacks for operands, control constructs, and calls. However, because the stacks are interdependent, additional book keeping about associated stack heights would be required. For the purpose of this specification, an interleaved representation is simpler.

Values

Values are represented by **themselves**.

Labels

Labels carry an argument arity n and their associated branch *target*, which is expressed syntactically as an **instruction** sequence:

$$\text{label} ::= \text{label}_n \{\text{instr}^*\}$$

Intuitively, $instr^*$ is the *continuation* to execute when the branch is taken, in place of the original control construct.

Note

For example, a loop label has the form

$$label_n\{(\text{loop } bt \dots)\}$$

When performing a branch to this label, this executes the loop, effectively restarting it from the beginning. Conversely, a simple block label has the form

$$label_n\{\epsilon\}$$

When branching, the empty continuation ends the targeted block, such that execution can proceed with consecutive instructions.

Call Frames

Call frames carry the return arity n of the respective function, hold the values of its **locals** (including arguments) in the order corresponding to their static **local indices**, and a reference to the function's own **module instance**:

$$\begin{aligned} callframe &::= frame_n\{frame\} \\ frame &::= \{locals (val^?)^*, module moduleinst\} \end{aligned}$$

Locals may be uninitialized, in which case they are empty. Locals are mutated by respective **variable instructions**.

Exception Handlers

Exception handlers are installed by **try_table** instructions and record the corresponding list of **catch clauses**:

$$handler ::= handler_n\{catch^*\}$$

The handlers on the stack are searched when an exception is **thrown**.

Conventions

- The meta variable L ranges over labels where clear from context.
- The meta variable f ranges over frame states where clear from context.
- The meta variable H ranges over exception handlers where clear from context.
- The following auxiliary definition takes a **block type** and looks up the **instruction type** that it denotes in the current frame:

$$\begin{aligned} instrtype_z(x) &= t_1^* \rightarrow t_2^* \quad \text{if } z.types[x] \approx \text{func } t_1^* \rightarrow t_2^* \\ instrtype_z(t^?) &= \epsilon \rightarrow t^? \end{aligned}$$

4.2.18 Administrative Instructions

Note

This section is only relevant for the **formal notation**.

In order to express the reduction of [traps](#), [calls](#), [exception handling](#), and [control instructions](#), the syntax of instructions is extended to include the following *administrative instructions*:

$$\begin{array}{lcl} \text{instr} & ::= & \dots \\ & | & \text{addrref} \\ & | & \text{label}_n\{\text{instr}^*\} \text{instr}^* \\ & | & \text{frame}_n\{\text{frame}\} \text{instr}^* \\ & | & \text{handler}_n\{\text{catch}^*\} \text{instr}^* \\ & | & \text{trap} \end{array}$$

An [address reference](#) represents an allocated [reference](#) value of respective form “on the stack”.

The label, frame, and handler instructions model [labels](#), [frames](#), and active [exception handlers](#), respectively, “on the stack”. Moreover, the administrative syntax maintains the nesting structure of the original [structured control instruction](#) or [function body](#) and their [instruction sequences](#).

The trap instruction represents the occurrence of a trap. Traps are bubbled up through nested instruction sequences, ultimately reducing the entire program to a single trap instruction, signalling abrupt termination.

Note

For example, the [reduction rule](#) for block is:

$$(\text{block } bt \text{ instr}^*) \hookrightarrow (\text{label}_n\{\epsilon\} \text{instr}^*)$$

if the [block type](#) bt denotes a [function type](#) $\text{func } t_1^m \rightarrow t_2^n$, such that n is the block’s result arity. This rule replaces the block with a label instruction, which can be interpreted as “pushing” the label on the stack. When its end is reached, i.e., the inner instruction sequence has been reduced to the empty sequence – or rather, a sequence of n [values](#) representing the results – then the label instruction is eliminated courtesy of its own [reduction rule](#):

$$(\text{label}_n\{\text{instr}^*\} \text{val}^*) \hookrightarrow \text{val}^*$$

This can be interpreted as removing the label from the stack and only leaving the locally accumulated operand values. Validation guarantees that n matches the number $|\text{val}^*|$ of resulting values at this point.

Configurations

A *configuration* describes the current computation. It consists of the computations’s *state* and the sequence of [instructions](#) left to execute. The state in turn consists of a global [store](#) and a current [frame](#) referring to the [module instance](#) in which the computation runs, i.e., where the current function originates from.

$$\begin{array}{lcl} \text{config} & ::= & \text{state}; \text{instr}^* \\ \text{state} & ::= & \text{store}; \text{frame} \end{array}$$

Note

The current version of WebAssembly is single-threaded, but configurations with multiple threads may be supported in the future.

4.3 Numerics

Numeric primitives are defined in a generic manner, by operators indexed over a bit width N .

Some operators are *non-deterministic*, because they can return one of several possible results (such as different NaN values). Technically, each operator thus returns a *set* of allowed values. For convenience, deterministic results are expressed as plain values, which are assumed to be identified with a respective singleton set.

Some operators are *partial*, because they are not defined on certain inputs. Technically, an empty set of results is returned for these inputs.

In formal notation, each operator is defined by equational clauses that apply in decreasing order of precedence. That is, the first clause that is applicable to the given arguments defines the result. In some cases, similar clauses are combined into one by using the notation \pm or \mp . When several of these placeholders occur in a single clause, then they must be resolved consistently: either the upper sign is chosen for all of them or the lower sign.

Note

For example, the `fcopysign` operator is defined as follows:

$$\begin{aligned}\text{fcopysign}_N(\pm p_1, \pm p_2) &= \pm p_1 \\ \text{fcopysign}_N(\pm p_1, \mp p_2) &= \mp p_1\end{aligned}$$

This definition is to be read as a shorthand for the following expansion of each clause into two separate ones:

$$\begin{aligned}\text{fcopysign}_N(+p_1, +p_2) &= +p_1 \\ \text{fcopysign}_N(-p_1, -p_2) &= -p_1 \\ \text{fcopysign}_N(+p_1, -p_2) &= -p_1 \\ \text{fcopysign}_N(-p_1, +p_2) &= +p_1\end{aligned}$$

Numeric operators are lifted to input sequences by applying the operator element-wise, returning a sequence of results. When there are multiple inputs, they must be of equal length.

$$op(c_1^n, \dots, c_k^n) = op(c_1^n[0], \dots, c_k^n[0]) \dots op(c_1^n[n-1], \dots, c_k^n[n-1])$$

Note

For example, the unary operator `fabs`, when given a sequence of floating-point values, return a sequence of floating-point results:

$$\text{fabs}_N(z^n) = \text{fabs}_N(z[0]) \dots \text{fabs}_N(z[n])$$

The binary operator `iadd`, when given two sequences of integers of the same length, n , return a sequence of integer results:

$$\text{iadd}_N(i_1^n, i_2^n) = \text{iadd}_N(i_1[0], i_2[0]) \dots \text{iadd}_N(i_1[n], i_2[n])$$

Conventions:

- The meta variable d is used to range over single bits.
- The meta variable p is used to range over (signless) **magnitudes** of floating-point values, including `nan` and ∞ .
- The meta variable q is used to range over (signless) *rational magnitudes*, excluding `nan` or ∞ .
- The notation f^{-1} denotes the inverse of a bijective function f .
- Truncation of rational values is written `trunc`($\pm q$), with the usual mathematical definition:

$$\text{trunc}(\pm q) = \pm i \quad (\text{if } i \in \mathbb{N} \wedge +q - 1 < i \leq +q)$$

- Saturation of integers is written `sat_uN`(i) and `sat_sN`(i). The arguments to these two functions range over arbitrary signed integers.

- Unsigned saturation, $\text{sat_u}_N(i)$ clamps i to between 0 and $2^N - 1$:

$$\begin{aligned}\text{sat_u}_N(i) &= 0 && (\text{if } i < 0) \\ \text{sat_u}_N(i) &= 2^N - 1 && (\text{if } i > 2^N - 1) \\ \text{sat_u}_N(i) &= i && (\text{otherwise})\end{aligned}$$

- Signed saturation, $\text{sat_s}_N(i)$ clamps i to between -2^{N-1} and $2^{N-1} - 1$:

$$\begin{aligned}\text{sat_s}_N(i) &= -2^{N-1} && (\text{if } i < -2^{N-1}) \\ \text{sat_s}_N(i) &= 2^{N-1} - 1 && (\text{if } i > 2^{N-1} - 1) \\ \text{sat_s}_N(i) &= i && (\text{otherwise})\end{aligned}$$

4.3.1 Representations

Numbers and numeric vectors have an underlying binary representation as a sequence of bits:

$$\begin{aligned}\text{bits}_{iN}(i) &= \text{ibits}_N(i) \\ \text{bits}_{fN}(z) &= \text{fbits}_N(z) \\ \text{bits}_{vN}(i) &= \text{ibits}_N(i)\end{aligned}$$

The first case of these applies to representations of both integer **value types** and **packed types**.

Each of these functions is a bijection, hence they are invertible.

Integers

Integers are represented as base two unsigned numbers:

$$\text{ibits}_N(i) = d_{N-1} \dots d_0 \quad (i = 2^{N-1} \cdot d_{N-1} + \dots + 2^0 \cdot d_0)$$

Boolean operators like \wedge , \vee , or $\underline{\vee}$ are lifted to bit sequences of equal length by applying them pointwise.

Floating-Point

Floating-point values are represented in the respective binary format defined by [IEEE 754²²](#) (Section 3.4):

$$\begin{aligned}\text{fbits}_N(\pm(1 + m \cdot 2^{-M}) \cdot 2^e) &= \text{fsign}(\pm) \text{ibits}_E(e + \text{fbias}_N) \text{ibits}_M(m) \\ \text{fbits}_N(\pm(0 + m \cdot 2^{-M}) \cdot 2^e) &= \text{fsign}(\pm) (0)^E \text{ibits}_M(m) \\ \text{fbits}_N(\pm\infty) &= \text{fsign}(\pm) (1)^E (0)^M \\ \text{fbits}_N(\pm\text{nan}(n)) &= \text{fsign}(\pm) (1)^E \text{ibits}_M(n) \\ \text{fbias}_N &= 2^{E-1} - 1 \\ \text{fsign}(+) &= 0 \\ \text{fsign}(-) &= 1\end{aligned}$$

where $M = \text{signif}(N)$ and $E = \text{expon}(N)$.

Vectors

Numeric vectors of type **vN** have the same underlying representation as an **iN**. They can also be interpreted as a sequence of numeric values packed into a **vN** with a particular *shape* txM , provided that $N = |t| \cdot M$.

$$\begin{aligned}\text{lanes}_{txM}(c) &= c_0 \dots c_{M-1} \\ (\text{where } w &= |t|/8 \\ &\wedge b^* = \text{bytes}_{iN}(c) \\ &\wedge c_i = \text{bytes}_t^{-1}(b^*[i \cdot w : w]))\end{aligned}$$

This function is a bijection on **iN**, hence it is invertible.

²² <https://ieeexplore.ieee.org/document/8766229>

Numeric values can be *packed* into lanes of a specific *lane type* and vice versa:

$$\begin{aligned} \text{pack}_{\text{numtype}}(c) &= c \\ \text{pack}_{\text{packtype}}(c) &= \text{wrap}_{|\text{unpack}(\text{packtype})|, |\text{packtype}|}(c) \\ \text{unpack}_{\text{numtype}}(c) &= c \\ \text{unpack}_{\text{packtype}}(c) &= \text{extend}_{|\text{packtype}|, |\text{unpack}(\text{packtype})|}^u(c) \end{aligned}$$

Storage

When a number is stored into *memory*, it is converted into a sequence of *bytes* in *little endian*²³ byte order:

$$\begin{aligned} \text{bytes}_t(i) &= \text{littleendian}(\text{bits}_t(i)) \\ \text{littleendian}(\epsilon) &= \epsilon \\ \text{littleendian}(d^8 \, d'^*) &= \text{littleendian}(d'^*) \, \text{ibits}_8^{-1}(d^8) \end{aligned}$$

Again these functions are invertible bijections.

4.3.2 Integer Operations

Sign Interpretation

Integer operators are defined on *iN* values. Operators that use a signed interpretation convert the value using the following definition, which takes the two's complement when the value lies in the upper half of the value range (i.e., its most significant bit is 1):

$$\begin{aligned} \text{signed}_N(i) &= i & (0 \leq i < 2^{N-1}) \\ \text{signed}_N(i) &= i - 2^N & (2^{N-1} \leq i < 2^N) \end{aligned}$$

This function is bijective, and hence invertible.

Boolean Interpretation

The integer result of predicates – i.e., *tests* and *relational* operators – is defined with the help of the following auxiliary function producing the value 1 or 0 depending on a condition.

$$\begin{aligned} \text{bool}(C) &= 1 & (\text{if } C) \\ \text{bool}(C) &= 0 & (\text{otherwise}) \end{aligned}$$

iadd_N(*i*₁, *i*₂)

- Return the result of adding *i*₁ and *i*₂ modulo 2^{*N*}.

$$\text{iadd}_N(i_1, i_2) = (i_1 + i_2) \bmod 2^N$$

isub_N(*i*₁, *i*₂)

- Return the result of subtracting *i*₂ from *i*₁ modulo 2^{*N*}.

$$\text{isub}_N(i_1, i_2) = (i_1 - i_2 + 2^N) \bmod 2^N$$

imul_N(*i*₁, *i*₂)

- Return the result of multiplying *i*₁ and *i*₂ modulo 2^{*N*}.

$$\text{imul}_N(i_1, i_2) = (i_1 \cdot i_2) \bmod 2^N$$

²³ <https://en.wikipedia.org/wiki/Endianness#Little-endian>

$\text{idiv_u}_N(i_1, i_2)$

- If i_2 is 0, then the result is undefined.
- Else, return the result of dividing i_1 by i_2 , truncated toward zero.

$$\begin{aligned}\text{idiv_u}_N(i_1, 0) &= \{\} \\ \text{idiv_u}_N(i_1, i_2) &= \text{trunc}(i_1/i_2)\end{aligned}$$

Note

This operator is **partial**.

 $\text{idiv_s}_N(i_1, i_2)$

- Let j_1 be the **signed interpretation** of i_1 .
- Let j_2 be the **signed interpretation** of i_2 .
- If j_2 is 0, then the result is undefined.
- Else if j_1 divided by j_2 is 2^{N-1} , then the result is undefined.
- Else, return the result of dividing j_1 by j_2 , truncated toward zero.

$$\begin{aligned}\text{idiv_s}_N(i_1, 0) &= \{\} \\ \text{idiv_s}_N(i_1, i_2) &= \{\} \quad (\text{if } \text{signed}_N(i_1)/\text{signed}_N(i_2) = 2^{N-1}) \\ \text{idiv_s}_N(i_1, i_2) &= \text{signed}_N^{-1}(\text{trunc}(\text{signed}_N(i_1)/\text{signed}_N(i_2)))\end{aligned}$$

Note

This operator is **partial**. Besides division by 0, the result of $(-2^{N-1})/(-1) = +2^{N-1}$ is not representable as an N -bit signed integer.

 $\text{irem_u}_N(i_1, i_2)$

- If i_2 is 0, then the result is undefined.
- Else, return the remainder of dividing i_1 by i_2 .

$$\begin{aligned}\text{irem_u}_N(i_1, 0) &= \{\} \\ \text{irem_u}_N(i_1, i_2) &= i_1 - i_2 \cdot \text{trunc}(i_1/i_2)\end{aligned}$$

Note

This operator is **partial**.

As long as both operators are defined, it holds that $i_1 = i_2 \cdot \text{idiv_u}(i_1, i_2) + \text{irem_u}(i_1, i_2)$.

 $\text{irem_s}_N(i_1, i_2)$

- Let j_1 be the **signed interpretation** of i_1 .
- Let j_2 be the **signed interpretation** of i_2 .
- If i_2 is 0, then the result is undefined.
- Else, return the remainder of dividing j_1 by j_2 , with the sign of the dividend j_1 .

$$\begin{aligned} \text{irem_s}_N(i_1, 0) &= \{\} \\ \text{irem_s}_N(i_1, i_2) &= \text{signed}_N^{-1}(j_1 - j_2 \cdot \text{trunc}(j_1/j_2)) \\ &\quad (\text{where } j_1 = \text{signed}_N(i_1) \wedge j_2 = \text{signed}_N(i_2)) \end{aligned}$$

Note

This operator is [partial](#).

As long as both operators are defined, it holds that $i_1 = i_2 \cdot \text{idiv_s}(i_1, i_2) + \text{irem_s}(i_1, i_2)$.

$\text{inot}_N(i)$

- Return the bitwise negation of i .

$$\text{inot}_N(i) = \text{ibits}_N^{-1}(\text{ibits}_N(i) \vee \text{ibits}_N(2^N - 1))$$

$\text{irev}_N(i)$

- Return the bitwise reversal of i .

$$\text{irev}_N(i) = \text{ibits}_N^{-1}((d^N[N - i])^{i \leq N}) \quad (\text{if } d^N = \text{ibits}_N(i))$$

$\text{iand}_N(i_1, i_2)$

- Return the bitwise conjunction of i_1 and i_2 .

$$\text{iand}_N(i_1, i_2) = \text{ibits}_N^{-1}(\text{ibits}_N(i_1) \wedge \text{ibits}_N(i_2))$$

$\text{iandnot}_N(i_1, i_2)$

- Return the bitwise conjunction of i_1 and the bitwise negation of i_2 .

$$\text{iandnot}_N(i_1, i_2) = \text{iand}_N(i_1, \text{inot}_N(i_2))$$

$\text{ior}_N(i_1, i_2)$

- Return the bitwise disjunction of i_1 and i_2 .

$$\text{ior}_N(i_1, i_2) = \text{ibits}_N^{-1}(\text{ibits}_N(i_1) \vee \text{ibits}_N(i_2))$$

$\text{ixor}_N(i_1, i_2)$

- Return the bitwise exclusive disjunction of i_1 and i_2 .

$$\text{ixor}_N(i_1, i_2) = \text{ibits}_N^{-1}(\text{ibits}_N(i_1) \vee \text{ibits}_N(i_2))$$

$\text{ishl}_N(i_1, i_2)$

- Let k be i_2 modulo N .
- Return the result of shifting i_1 left by k bits, modulo 2^N .

$$\text{ishl}_N(i_1, i_2) = \text{ibits}_N^{-1}(d_2^{N-k} 0^k) \quad (\text{if } \text{ibits}_N(i_1) = d_1^k d_2^{N-k} \wedge k = i_2 \bmod N)$$

$\text{ishr_u}_N(i_1, i_2)$

- Let k be i_2 modulo N .
- Return the result of shifting i_1 right by k bits, extended with 0 bits.

$$\text{ishr_u}_N(i_1, i_2) = \text{ibits}_N^{-1}(0^k d_1^{N-k}) \quad (\text{if } \text{ibits}_N(i_1) = d_1^{N-k} d_2^k \wedge k = i_2 \bmod N)$$

$\text{ishr}_{\text{S}_N}(i_1, i_2)$

- Let k be i_2 modulo N .
- Return the result of shifting i_1 right by k bits, extended with the most significant bit of the original value.

$$\text{ishr}_{\text{S}_N}(i_1, i_2) = \text{ibits}_N^{-1}(d_0^{k+1} d_1^{N-k-1}) \quad (\text{if } \text{ibits}_N(i_1) = d_0 d_1^{N-k-1} d_2^k \wedge k = i_2 \bmod N)$$

$\text{irotl}_N(i_1, i_2)$

- Let k be i_2 modulo N .
- Return the result of rotating i_1 left by k bits.

$$\text{irotl}_N(i_1, i_2) = \text{ibits}_N^{-1}(d_2^{N-k} d_1^k) \quad (\text{if } \text{ibits}_N(i_1) = d_1^k d_2^{N-k} \wedge k = i_2 \bmod N)$$

$\text{irot}_N(i_1, i_2)$

- Let k be i_2 modulo N .
- Return the result of rotating i_1 right by k bits.

$$\text{irot}_N(i_1, i_2) = \text{ibits}_N^{-1}(d_2^k d_1^{N-k}) \quad (\text{if } \text{ibits}_N(i_1) = d_1^{N-k} d_2^k \wedge k = i_2 \bmod N)$$

$\text{iclz}_N(i)$

- Return the count of leading zero bits in i ; all bits are considered leading zeros if i is 0.

$$\text{iclz}_N(i) = k \quad (\text{if } \text{ibits}_N(i) = 0^k (1 d^*)^?)$$

$\text{ictz}_N(i)$

- Return the count of trailing zero bits in i ; all bits are considered trailing zeros if i is 0.

$$\text{ictz}_N(i) = k \quad (\text{if } \text{ibits}_N(i) = (d^* 1)^? 0^k)$$

$\text{ipopcnt}_N(i)$

- Return the count of non-zero bits in i .

$$\text{ipopcnt}_N(i) = k \quad (\text{if } \text{ibits}_N(i) = (0^* 1)^k 0^*)$$

$\text{ieqz}_N(i)$

- Return 1 if i is zero, 0 otherwise.

$$\text{ieqz}_N(i) = \text{bool}(i = 0)$$

$\text{inez}_N(i)$

- Return 0 if i is zero, 1 otherwise.

$$\text{inez}_N(i) = \text{bool}(i \neq 0)$$

$\text{ieq}_N(i_1, i_2)$

- Return 1 if i_1 equals i_2 , 0 otherwise.

$$\text{ieq}_N(i_1, i_2) = \text{bool}(i_1 = i_2)$$

$\text{ine}_N(i_1, i_2)$

- Return 1 if i_1 does not equal i_2 , 0 otherwise.

$$\text{ine}_N(i_1, i_2) = \text{bool}(i_1 \neq i_2)$$

$\text{ilt_u}_N(i_1, i_2)$

- Return 1 if i_1 is less than i_2 , 0 otherwise.

$$\text{ilt_u}_N(i_1, i_2) = \text{bool}(i_1 < i_2)$$

$\text{ilt_s}_N(i_1, i_2)$

- Let j_1 be the [signed interpretation](#) of i_1 .
- Let j_2 be the [signed interpretation](#) of i_2 .
- Return 1 if j_1 is less than j_2 , 0 otherwise.

$$\text{ilt_s}_N(i_1, i_2) = \text{bool}(\text{signed}_N(i_1) < \text{signed}_N(i_2))$$

$\text{igt_u}_N(i_1, i_2)$

- Return 1 if i_1 is greater than i_2 , 0 otherwise.

$$\text{igt_u}_N(i_1, i_2) = \text{bool}(i_1 > i_2)$$

$\text{igt_s}_N(i_1, i_2)$

- Let j_1 be the [signed interpretation](#) of i_1 .
- Let j_2 be the [signed interpretation](#) of i_2 .
- Return 1 if j_1 is greater than j_2 , 0 otherwise.

$$\text{igt_s}_N(i_1, i_2) = \text{bool}(\text{signed}_N(i_1) > \text{signed}_N(i_2))$$

$\text{ile_u}_N(i_1, i_2)$

- Return 1 if i_1 is less than or equal to i_2 , 0 otherwise.

$$\text{ile_u}_N(i_1, i_2) = \text{bool}(i_1 \leq i_2)$$

$\text{ile_s}_N(i_1, i_2)$

- Let j_1 be the [signed interpretation](#) of i_1 .
- Let j_2 be the [signed interpretation](#) of i_2 .
- Return 1 if j_1 is less than or equal to j_2 , 0 otherwise.

$$\text{ile_s}_N(i_1, i_2) = \text{bool}(\text{signed}_N(i_1) \leq \text{signed}_N(i_2))$$

$\text{ige_u}_N(i_1, i_2)$

- Return 1 if i_1 is greater than or equal to i_2 , 0 otherwise.

$$\text{ige_u}_N(i_1, i_2) = \text{bool}(i_1 \geq i_2)$$

$\text{ige_s}_N(i_1, i_2)$

- Let j_1 be the signed interpretation of i_1 .
- Let j_2 be the signed interpretation of i_2 .
- Return 1 if j_1 is greater than or equal to j_2 , 0 otherwise.

$$\text{ige_s}_N(i_1, i_2) = \text{bool}(\text{signed}_N(i_1) \geq \text{signed}_N(i_2))$$

$\text{iextend}_M\text{_s}_N(i)$

- Let j be the result of computing $\text{wrap}_{N,M}(i)$.
- Return $\text{extend}^s_{M,N}(j)$.

$$\text{iextend}_M\text{_s}_N(i) = \text{extend}^s_{M,N}(\text{wrap}_{N,M}(i))$$

$\text{ibitselect}_N(i_1, i_2, i_3)$

- Let j_1 be the bitwise conjunction of i_1 and i_3 .
- Let j'_3 be the bitwise negation of i_3 .
- Let j_2 be the bitwise conjunction of i_2 and j'_3 .
- Return the bitwise disjunction of j_1 and j_2 .

$$\text{ibitselect}_N(i_1, i_2, i_3) = \text{ior}_N(\text{iand}_N(i_1, i_3), \text{iand}_N(i_2, \text{inot}_N(i_3)))$$

$\text{iabs}_N(i)$

- Let j be the signed interpretation of i .
- If j is greater than or equal to 0, then return i .
- Else return the negation of j , modulo 2^N .

$$\begin{aligned} \text{iabs}_N(i) &= i && (\text{if } \text{signed}_N(i) \geq 0) \\ \text{iabs}_N(i) &= -\text{signed}_N(i) \bmod 2^N && (\text{otherwise}) \end{aligned}$$

$\text{ineg}_N(i)$

- Return the result of negating i , modulo 2^N .

$$\text{ineg}_N(i) = (2^N - i) \bmod 2^N$$

$\text{imin_u}_N(i_1, i_2)$

- Return i_1 if $\text{ilt_u}_N(i_1, i_2)$ is 1, return i_2 otherwise.

$$\begin{aligned} \text{imin_u}_N(i_1, i_2) &= i_1 && (\text{if } \text{ilt_u}_N(i_1, i_2) = 1) \\ \text{imin_u}_N(i_1, i_2) &= i_2 && (\text{otherwise}) \end{aligned}$$

$\text{imin_s}_N(i_1, i_2)$

- Return i_1 if $\text{ilt_s}_N(i_1, i_2)$ is 1, return i_2 otherwise.

$$\begin{aligned} \text{imin_s}_N(i_1, i_2) &= i_1 && (\text{if } \text{ilt_s}_N(i_1, i_2) = 1) \\ \text{imin_s}_N(i_1, i_2) &= i_2 && (\text{otherwise}) \end{aligned}$$

$\text{imax_u}_N(i_1, i_2)$

- Return i_1 if $\text{igt_u}_N(i_1, i_2)$ is 1, return i_2 otherwise.

$$\begin{aligned} \text{imax_u}_N(i_1, i_2) &= i_1 && (\text{if } \text{igt_u}_N(i_1, i_2) = 1) \\ \text{imax_u}_N(i_1, i_2) &= i_2 && (\text{otherwise}) \end{aligned}$$

$\text{imax_s}_N(i_1, i_2)$

- Return i_1 if $\text{igt_s}_N(i_1, i_2)$ is 1, return i_2 otherwise.

$$\begin{aligned}\text{imax_s}_N(i_1, i_2) &= i_1 && (\text{if } \text{igt_s}_N(i_1, i_2) = 1) \\ \text{imax_s}_N(i_1, i_2) &= i_2 && (\text{otherwise})\end{aligned}$$

$\text{iadd_sat_u}_N(i_1, i_2)$

- Let i be the result of adding i_1 and i_2 .
- Return $\text{sat_u}_N(i)$.

$$\text{iadd_sat_u}_N(i_1, i_2) = \text{sat_u}_N(i_1 + i_2)$$

$\text{iadd_sat_s}_N(i_1, i_2)$

- Let j_1 be the signed interpretation of i_1
- Let j_2 be the signed interpretation of i_2
- Let j be the result of adding j_1 and j_2 .
- Return the value whose signed interpretation is $\text{sat_s}_N(j)$.

$$\text{iadd_sat_s}_N(i_1, i_2) = \text{signed}_N^{-1}(\text{sat_s}_N(\text{signed}_N(i_1) + \text{signed}_N(i_2)))$$

$\text{isub_sat_u}_N(i_1, i_2)$

- Let i be the result of subtracting i_2 from i_1 .
- Return $\text{sat_u}_N(i)$.

$$\text{isub_sat_u}_N(i_1, i_2) = \text{sat_u}_N(i_1 - i_2)$$

$\text{isub_sat_s}_N(i_1, i_2)$

- Let j_1 be the signed interpretation of i_1
- Let j_2 be the signed interpretation of i_2
- Let j be the result of subtracting j_2 from j_1 .
- Return the value whose signed interpretation is $\text{sat_s}_N(j)$.

$$\text{isub_sat_s}_N(i_1, i_2) = \text{signed}_N^{-1}(\text{sat_s}_N(\text{signed}_N(i_1) - \text{signed}_N(i_2)))$$

$\text{iavgr_u}_N(i_1, i_2)$

- Let j be the result of adding i_1 , i_2 , and 1.
- Return the result of dividing j by 2, truncated toward zero.

$$\text{iavgr_u}_N(i_1, i_2) = \text{trunc}((i_1 + i_2 + 1)/2)$$

$\text{iq15mulrsat_s}_N(i_1, i_2)$

- Return the whose signed interpretation is the result of $\text{sat_s}_N(\text{ishr_s}_N(i_1 \cdot i_2 + 2^{14}, 15))$.

$$\text{iq15mulrsat_s}_N(i_1, i_2) = \text{signed}_N^{-1}(\text{sat_s}_N(\text{ishr_s}_N(i_1 \cdot i_2 + 2^{14}, 15)))$$

4.3.3 Floating-Point Operations

Floating-point arithmetic follows the [IEEE 754²⁴](#) standard, with the following qualifications:

- All operators use round-to-nearest ties-to-even, except where otherwise specified. Non-default directed rounding attributes are not supported.
- Following the recommendation that operators propagate NaN payloads from their operands is permitted but not required.
- All operators use “non-stop” mode, and floating-point exceptions are not otherwise observable. In particular, neither alternate floating-point exception handling attributes nor operators on status flags are supported. There is no observable difference between quiet and signalling NaNs.

Note

Some of these limitations may be lifted in future versions of WebAssembly.

Rounding

Rounding always is round-to-nearest ties-to-even, in correspondence with [IEEE 754²⁵](#) (Section 4.3.1).

An *exact* floating-point number is a rational number that is exactly representable as a floating-point number of given bit width N .

A *limit* number for a given floating-point bit width N is a positive or negative number whose magnitude is the smallest power of 2 that is not exactly representable as a floating-point number of width N (that magnitude is 2^{128} for $N = 32$ and 2^{1024} for $N = 64$).

A *candidate* number is either an exact floating-point number or a positive or negative limit number for the given bit width N .

A *candidate pair* is a pair z_1, z_2 of candidate numbers, such that no candidate number exists that lies between the two.

A real number r is converted to a floating-point value of bit width N as follows:

- If r is 0, then return $+0$.
- Else if r is an exact floating-point number, then return r .
- Else if r greater than or equal to the positive limit, then return $+\infty$.
- Else if r is less than or equal to the negative limit, then return $-\infty$.
- Else if z_1 and z_2 are a candidate pair such that $z_1 < r < z_2$, then:
 - If $|r - z_1| < |r - z_2|$, then let z be z_1 .
 - Else if $|r - z_1| > |r - z_2|$, then let z be z_2 .
 - Else if $|r - z_1| = |r - z_2|$ and the [significand](#) of z_1 is even, then let z be z_1 .
 - Else, let z be z_2 .
- If z is 0, then:
 - If $r < 0$, then return -0 .
 - Else, return $+0$.
- Else if z is a limit number, then:
 - If $r < 0$, then return $-\infty$.
 - Else, return $+\infty$.

²⁴ <https://ieeexplore.ieee.org/document/8766229>

²⁵ <https://ieeexplore.ieee.org/document/8766229>

- Else, return z .

$$\begin{aligned}
 \text{float}_N(0) &= +0 \\
 \text{float}_N(r) &= r && (\text{if } r \in \text{exact}_N) \\
 \text{float}_N(r) &= +\infty && (\text{if } r \geq +\text{limit}_N) \\
 \text{float}_N(r) &= -\infty && (\text{if } r \leq -\text{limit}_N) \\
 \text{float}_N(r) &= \text{closest}_N(r, z_1, z_2) && (\text{if } z_1 < r < z_2 \wedge (z_1, z_2) \in \text{candidatepair}_N) \\
 \text{closest}_N(r, z_1, z_2) &= \text{rectify}_N(r, z_1) && (\text{if } |r - z_1| < |r - z_2|) \\
 \text{closest}_N(r, z_1, z_2) &= \text{rectify}_N(r, z_2) && (\text{if } |r - z_1| > |r - z_2|) \\
 \text{closest}_N(r, z_1, z_2) &= \text{rectify}_N(r, z_1) && (\text{if } |r - z_1| = |r - z_2| \wedge \text{even}_N(z_1)) \\
 \text{closest}_N(r, z_1, z_2) &= \text{rectify}_N(r, z_2) && (\text{if } |r - z_1| = |r - z_2| \wedge \text{even}_N(z_2)) \\
 \text{rectify}_N(r, \pm\text{limit}_N) &= \pm\infty \\
 \text{rectify}_N(r, 0) &= +0 && (r \geq 0) \\
 \text{rectify}_N(r, 0) &= -0 && (r < 0) \\
 \text{rectify}_N(r, z) &= z
 \end{aligned}$$

where:

$$\begin{aligned}
 \text{exact}_N &= f_{N \cap \mathbb{Q}} \\
 \text{limit}_N &= 2^{2^{\text{expon}(N)} - 1} \\
 \text{candidate}_N &= \text{exact}_N \cup \{+\text{limit}_N, -\text{limit}_N\} \\
 \text{candidatepair}_N &= \{(z_1, z_2) \in \text{candidate}_N^2 \mid z_1 < z_2 \wedge \forall z \in \text{candidate}_N, z \leq z_1 \vee z \geq z_2\} \\
 \text{even}_N((d + m \cdot 2^{-M}) \cdot 2^e) &\Leftrightarrow m \bmod 2 = 0 \\
 \text{even}_N(\pm\text{limit}_N) &\Leftrightarrow \text{true}
 \end{aligned}$$

NaN Propagation

When the result of a floating-point operator other than `fneg`, `fabs`, or `fcopysign` is a NaN, then its sign is non-deterministic and the `payload` is computed as follows:

- If the payload of all NaN inputs to the operator is `canonical` (including the case that there are no NaN inputs), then the payload of the output is canonical as well.
- Otherwise the payload is picked non-deterministically among all `arithmetic NaNs`; that is, its most significant bit is 1 and all others are unspecified.
- In the `deterministic profile`, however, a positive canonical NaNs is reliably produced in the latter case.

The non-deterministic result is expressed by the following auxiliary function producing a set of allowed outputs from a set of inputs:

$$\begin{aligned}
 \text{nans}_N\{z^*\} &= \{+\text{nan}(\text{canon}_N)\} \\
 \text{[!DET]} \quad \text{nans}_N\{z^*\} &= \{+\text{nan}(n), -\text{nan}(n) \mid n = \text{canon}_N\} && (\text{if } \{z^*\} \subseteq \{+\text{nan}(\text{canon}_N), -\text{nan}(\text{canon}_N)\}) \\
 \text{[!DET]} \quad \text{nans}_N\{z^*\} &= \{+\text{nan}(n), -\text{nan}(n) \mid n \geq \text{canon}_N\} && (\text{if } \{z^*\} \not\subseteq \{+\text{nan}(\text{canon}_N), -\text{nan}(\text{canon}_N)\})
 \end{aligned}$$

`faddN(z_1, z_2)`

- If either z_1 or z_2 is a NaN, then return an element of `nansN{ z_1, z_2 }`.
- Else if both z_1 and z_2 are infinities of opposite signs, then return an element of `nansN{}`.
- Else if both z_1 and z_2 are infinities of equal sign, then return that infinity.
- Else if either z_1 or z_2 is an infinity, then return that infinity.
- Else if both z_1 and z_2 are zeroes of opposite sign, then return positive zero.
- Else if both z_1 and z_2 are zeroes of equal sign, then return that zero.
- Else if either z_1 or z_2 is a zero, then return the other operand.
- Else if both z_1 and z_2 are values with the same magnitude but opposite signs, then return positive zero.
- Else return the result of adding z_1 and z_2 , `rounded` to the nearest representable value.

$\text{fadd}_N(\pm\text{nan}(n), z_2)$	$= \text{nans}_N\{\pm\text{nan}(n), z_2\}$
$\text{fadd}_N(z_1, \pm\text{nan}(n))$	$= \text{nans}_N\{\pm\text{nan}(n), z_1\}$
$\text{fadd}_N(\pm\infty, \mp\infty)$	$= \text{nans}_N\{\}$
$\text{fadd}_N(\pm\infty, \pm\infty)$	$= \pm\infty$
$\text{fadd}_N(z_1, \pm\infty)$	$= \pm\infty$
$\text{fadd}_N(\pm\infty, z_2)$	$= \pm\infty$
$\text{fadd}_N(\pm 0, \mp 0)$	$= +0$
$\text{fadd}_N(\pm 0, \pm 0)$	$= \pm 0$
$\text{fadd}_N(z_1, \pm 0)$	$= z_1$
$\text{fadd}_N(\pm 0, z_2)$	$= z_2$
$\text{fadd}_N(\pm q, \mp q)$	$= +0$
$\text{fadd}_N(z_1, z_2)$	$= \text{float}_N(z_1 + z_2)$

$\text{fsub}_N(z_1, z_2)$

- If either z_1 or z_2 is a NaN, then return an element of $\text{nans}_N\{z_1, z_2\}$.
- Else if both z_1 and z_2 are infinities of equal signs, then return an element of $\text{nans}_N\{\}$.
- Else if both z_1 and z_2 are infinities of opposite sign, then return z_1 .
- Else if z_1 is an infinity, then return that infinity.
- Else if z_2 is an infinity, then return that infinity negated.
- Else if both z_1 and z_2 are zeroes of equal sign, then return positive zero.
- Else if both z_1 and z_2 are zeroes of opposite sign, then return z_1 .
- Else if z_2 is a zero, then return z_1 .
- Else if z_1 is a zero, then return z_2 negated.
- Else if both z_1 and z_2 are the same value, then return positive zero.
- Else return the result of subtracting z_2 from z_1 , rounded to the nearest representable value.

$\text{fsub}_N(\pm\text{nan}(n), z_2)$	$= \text{nans}_N\{\pm\text{nan}(n), z_2\}$
$\text{fsub}_N(z_1, \pm\text{nan}(n))$	$= \text{nans}_N\{\pm\text{nan}(n), z_1\}$
$\text{fsub}_N(\pm\infty, \pm\infty)$	$= \text{nans}_N\{\}$
$\text{fsub}_N(\pm\infty, \mp\infty)$	$= \pm\infty$
$\text{fsub}_N(z_1, \pm\infty)$	$= \mp\infty$
$\text{fsub}_N(\pm\infty, z_2)$	$= \pm\infty$
$\text{fsub}_N(\pm 0, \pm 0)$	$= +0$
$\text{fsub}_N(\pm 0, \mp 0)$	$= \pm 0$
$\text{fsub}_N(z_1, \pm 0)$	$= z_1$
$\text{fsub}_N(\pm 0, \pm q_2)$	$= \mp q_2$
$\text{fsub}_N(\pm q, \pm q)$	$= +0$
$\text{fsub}_N(z_1, z_2)$	$= \text{float}_N(z_1 - z_2)$

Note

Up to the non-determinism regarding NaNs, it always holds that $\text{fsub}_N(z_1, z_2) = \text{fadd}_N(z_1, \text{fneg}_N(z_2))$.

$\text{fmul}_N(z_1, z_2)$

- If either z_1 or z_2 is a NaN, then return an element of $\text{nans}_N\{z_1, z_2\}$.
- Else if one of z_1 and z_2 is a zero and the other an infinity, then return an element of $\text{nans}_N\{\}$.
- Else if both z_1 and z_2 are infinities of equal sign, then return positive infinity.
- Else if both z_1 and z_2 are infinities of opposite sign, then return negative infinity.
- Else if either z_1 or z_2 is an infinity and the other a value with equal sign, then return positive infinity.

- Else if either z_1 or z_2 is an infinity and the other a value with opposite sign, then return negative infinity.
- Else if both z_1 and z_2 are zeroes of equal sign, then return positive zero.
- Else if both z_1 and z_2 are zeroes of opposite sign, then return negative zero.
- Else return the result of multiplying z_1 and z_2 , **rounded** to the nearest representable value.

$\text{fmul}_N(\pm\text{nan}(n), z_2)$	$= \text{nans}_N\{\pm\text{nan}(n), z_2\}$
$\text{fmul}_N(z_1, \pm\text{nan}(n))$	$= \text{nans}_N\{\pm\text{nan}(n), z_1\}$
$\text{fmul}_N(\pm\infty, \pm 0)$	$= \text{nans}_N\{\}$
$\text{fmul}_N(\pm\infty, \mp 0)$	$= \text{nans}_N\{\}$
$\text{fmul}_N(\pm 0, \pm\infty)$	$= \text{nans}_N\{\}$
$\text{fmul}_N(\pm 0, \mp\infty)$	$= \text{nans}_N\{\}$
$\text{fmul}_N(\pm\infty, \pm\infty)$	$= +\infty$
$\text{fmul}_N(\pm\infty, \mp\infty)$	$= -\infty$
$\text{fmul}_N(\pm q_1, \pm\infty)$	$= +\infty$
$\text{fmul}_N(\pm q_1, \mp\infty)$	$= -\infty$
$\text{fmul}_N(\pm\infty, \pm q_2)$	$= +\infty$
$\text{fmul}_N(\pm\infty, \mp q_2)$	$= -\infty$
$\text{fmul}_N(\pm 0, \pm 0)$	$= +0$
$\text{fmul}_N(\pm 0, \mp 0)$	$= -0$
$\text{fmul}_N(z_1, z_2)$	$= \text{float}_N(z_1 \cdot z_2)$

$\text{fdiv}_N(z_1, z_2)$

- If either z_1 or z_2 is a NaN, then return an element of $\text{nans}_N\{z_1, z_2\}$.
- Else if both z_1 and z_2 are infinities, then return an element of $\text{nans}_N\{\}$.
- Else if both z_1 and z_2 are zeroes, then return an element of $\text{nans}_N\{z_1, z_2\}$.
- Else if z_1 is an infinity and z_2 a value with equal sign, then return positive infinity.
- Else if z_1 is an infinity and z_2 a value with opposite sign, then return negative infinity.
- Else if z_2 is an infinity and z_1 a value with equal sign, then return positive zero.
- Else if z_2 is an infinity and z_1 a value with opposite sign, then return negative zero.
- Else if z_1 is a zero and z_2 a value with equal sign, then return positive zero.
- Else if z_1 is a zero and z_2 a value with opposite sign, then return negative zero.
- Else if z_2 is a zero and z_1 a value with equal sign, then return positive infinity.
- Else if z_2 is a zero and z_1 a value with opposite sign, then return negative infinity.
- Else return the result of dividing z_1 by z_2 , **rounded** to the nearest representable value.

$\text{fdiv}_N(\pm\text{nan}(n), z_2)$	$= \text{nans}_N\{\pm\text{nan}(n), z_2\}$
$\text{fdiv}_N(z_1, \pm\text{nan}(n))$	$= \text{nans}_N\{\pm\text{nan}(n), z_1\}$
$\text{fdiv}_N(\pm\infty, \pm\infty)$	$= \text{nans}_N\{\}$
$\text{fdiv}_N(\pm\infty, \mp\infty)$	$= \text{nans}_N\{\}$
$\text{fdiv}_N(\pm 0, \pm 0)$	$= \text{nans}_N\{\}$
$\text{fdiv}_N(\pm 0, \mp 0)$	$= \text{nans}_N\{\}$
$\text{fdiv}_N(\pm\infty, \pm q_2)$	$= +\infty$
$\text{fdiv}_N(\pm\infty, \mp q_2)$	$= -\infty$
$\text{fdiv}_N(\pm q_1, \pm\infty)$	$= +0$
$\text{fdiv}_N(\pm q_1, \mp\infty)$	$= -0$
$\text{fdiv}_N(\pm 0, \pm q_2)$	$= +0$
$\text{fdiv}_N(\pm 0, \mp q_2)$	$= -0$
$\text{fdiv}_N(\pm q_1, \pm 0)$	$= +\infty$
$\text{fdiv}_N(\pm q_1, \mp 0)$	$= -\infty$
$\text{fdiv}_N(z_1, z_2)$	$= \text{float}_N(z_1/z_2)$

$\text{fma}_N(z_1, z_2, z_3)$

The function `fma` is the same as *fusedMultiplyAdd* defined by IEEE 754²⁶ (Section 5.4.1). It computes $(z_1 \cdot z_2) + z_3$ as if with unbounded range and precision, rounding only once for the final result.

- If either z_1 or z_2 or z_3 is a NaN, return an element of $\text{nans}_N\{z_1, z_2, z_3\}$.
- Else if either z_1 or z_2 is a zero and the other is an infinity, then return an element of $\text{nans}_N\{\}$.
- Else if both z_1 or z_2 are infinities of equal sign, and z_3 is a negative infinity, then return an element of $\text{nans}_N\{\}$.
- Else if both z_1 or z_2 are infinities of opposite sign, and z_3 is a positive infinity, then return an element of $\text{nans}_N\{\}$.
- Else if either z_1 or z_2 is an infinity and the other is a value of the same sign, and z_3 is a negative infinity, then return an element of $\text{nans}_N\{\}$.
- Else if either z_1 or z_2 is an infinity and the other is a value of the opposite sign, and z_3 is a positive infinity, then return an element of $\text{nans}_N\{\}$.
- Else if both z_1 and z_2 are zeroes of the same sign and z_3 is a zero, then return positive zero.
- Else if both z_1 and z_2 are zeroes of the opposite sign and z_3 is a positive zero, then return positive zero.
- Else if both z_1 and z_2 are zeroes of the opposite sign and z_3 is a negative zero, then return negative zero.
- Else return the result of multiplying z_1 and z_2 , adding z_3 to the intermediate, and the final result ref:rounded <aux-ieee> to the nearest representable value.

$\text{fma}_N(\pm\text{nan}(n), z_2, z_3)$	$= \text{nans}_N\{\pm\text{nan}(n), z_2, z_3\}$
$\text{fma}_N(z_1, \pm\text{nan}(n), z_3)$	$= \text{nans}_N\{\pm\text{nan}(n), z_1, z_3\}$
$\text{fma}_N(z_1, z_2, \pm\text{nan}(n))$	$= \text{nans}_N\{\pm\text{nan}(n), z_1, z_2\}$
$\text{fma}_N(\pm\infty, \pm 0, z_3)$	$= \text{nans}_N\{\}$
$\text{fma}_N(\pm\infty, \mp 0, z_3)$	$= \text{nans}_N\{\}$
$\text{fma}_N(\pm\infty, \pm\infty, -\infty)$	$= \text{nans}_N\{\}$
$\text{fma}_N(\pm\infty, \mp\infty, +\infty)$	$= \text{nans}_N\{\}$
$\text{fma}_N(\pm q_1, \pm\infty, -\infty)$	$= \text{nans}_N\{\}$
$\text{fma}_N(\pm q_1, \mp\infty, +\infty)$	$= \text{nans}_N\{\}$
$\text{fma}_N(\pm\infty, \pm q_1, -\infty)$	$= \text{nans}_N\{\}$
$\text{fma}_N(\mp\infty, \pm q_1, +\infty)$	$= \text{nans}_N\{\}$
$\text{fma}_N(\pm 0, \pm 0, \mp 0)$	$= +0$
$\text{fma}_N(\pm 0, \pm 0, \pm 0)$	$= +0$
$\text{fma}_N(\pm 0, \mp 0, +0)$	$= +0$
$\text{fma}_N(\pm 0, \mp 0, -0)$	$= -0$
$\text{fma}_N(z_1, z_2, z_3)$	$= \text{float}_N(z_1 \cdot z_2 + z_3)$

$\text{fmin}_N(z_1, z_2)$

- If either z_1 or z_2 is a NaN, then return an element of $\text{nans}_N\{z_1, z_2\}$.
- Else if either z_1 or z_2 is a negative infinity, then return negative infinity.
- Else if either z_1 or z_2 is a positive infinity, then return the other value.
- Else if both z_1 and z_2 are zeroes of opposite signs, then return negative zero.
- Else return the smaller value of z_1 and z_2 .

²⁶ <https://ieeexplore.ieee.org/document/8766229>

$$\begin{aligned}
fmin_N(\pm nan(n), z_2) &= nans_N\{\pm nan(n), z_2\} \\
fmin_N(z_1, \pm nan(n)) &= nans_N\{\pm nan(n), z_1\} \\
fmin_N(+\infty, z_2) &= z_2 \\

fmax_N(\pm 0, \mp 0) &= +0 \\
fmax_N(z_1, z_2) &= z_1 && (\text{if } z_1 \geq z_2) \\
fmax_N(z_1, z_2) &= z_2 && (\text{if } z_2 \geq z_1)
\end{aligned}$$

$fcopysign_N(z_1, z_2)$

- If z_1 and z_2 have the same sign, then return z_1 .
- Else return z_1 with negated sign.

$$\begin{aligned}
fcopysign_N(\pm p_1, \pm p_2) &= \pm p_1 \\
fcopysign_N(\pm p_1, \mp p_2) &= \mp p_1
\end{aligned}$$

$fabs_N(z)$

- If z is a NaN, then return z with positive sign.
- Else if z is an infinity, then return positive infinity.
- Else if z is a zero, then return positive zero.
- Else if z is a positive value, then z .
- Else return z negated.

$$\begin{aligned}
fabs_N(\pm nan(n)) &= +nan(n) \\
fabs_N(\pm \infty) &= +\infty \\
fabs_N(\pm 0) &= +0 \\
fabs_N(\pm q) &= +q
\end{aligned}$$

$fneg_N(z)$

- If z is a NaN, then return z with negated sign.
- Else if z is an infinity, then return that infinity negated.
- Else if z is a zero, then return that zero negated.
- Else return z negated.

$$\begin{aligned}
\text{fneg}_N(\pm\text{nan}(n)) &= \mp\text{nan}(n) \\
\text{fneg}_N(\pm\infty) &= \mp\infty \\
\text{fneg}_N(\pm 0) &= \mp 0 \\
\text{fneg}_N(\pm q) &= \mp q
\end{aligned}$$

$\text{fsqrt}_N(z)$

- If z is a NaN, then return an element of $\text{nans}_N\{z\}$.
- Else if z is negative infinity, then return an element of $\text{nans}_N\{\}$.
- Else if z is positive infinity, then return positive infinity.
- Else if z is a zero, then return that zero.
- Else if z has a negative sign, then return an element of $\text{nans}_N\{\}$.
- Else return the square root of z .

$$\begin{aligned}
\text{fsqrt}_N(\pm\text{nan}(n)) &= \text{nans}_N\{\pm\text{nan}(n)\} \\
\text{fsqrt}_N(-\infty) &= \text{nans}_N\{\} \\
\text{fsqrt}_N(+\infty) &= +\infty \\
\text{fsqrt}_N(\pm 0) &= \pm 0 \\
\text{fsqrt}_N(-q) &= \text{nans}_N\{\} \\
\text{fsqrt}_N(+q) &= \text{float}_N(\sqrt{q})
\end{aligned}$$

$\text{fceil}_N(z)$

- If z is a NaN, then return an element of $\text{nans}_N\{z\}$.
- Else if z is an infinity, then return z .
- Else if z is a zero, then return z .
- Else if z is smaller than 0 but greater than -1 , then return negative zero.
- Else return the smallest integral value that is not smaller than z .

$$\begin{aligned}
\text{fceil}_N(\pm\text{nan}(n)) &= \text{nans}_N\{\pm\text{nan}(n)\} \\
\text{fceil}_N(\pm\infty) &= \pm\infty \\
\text{fceil}_N(\pm 0) &= \pm 0 \\
\text{fceil}_N(-q) &= -0 && (\text{if } -1 < -q < 0) \\
\text{fceil}_N(\pm q) &= \text{float}_N(i) && (\text{if } \pm q \leq i < \pm q + 1)
\end{aligned}$$

$\text{ffloor}_N(z)$

- If z is a NaN, then return an element of $\text{nans}_N\{z\}$.
- Else if z is an infinity, then return z .
- Else if z is a zero, then return z .
- Else if z is greater than 0 but smaller than 1, then return positive zero.
- Else return the largest integral value that is not larger than z .

$$\begin{aligned}
\text{ffloor}_N(\pm\text{nan}(n)) &= \text{nans}_N\{\pm\text{nan}(n)\} \\
\text{ffloor}_N(\pm\infty) &= \pm\infty \\
\text{ffloor}_N(\pm 0) &= \pm 0 \\
\text{ffloor}_N(+q) &= +0 && (\text{if } 0 < +q < 1) \\
\text{ffloor}_N(\pm q) &= \text{float}_N(i) && (\text{if } \pm q - 1 < i \leq \pm q)
\end{aligned}$$

$\text{ftrunc}_N(z)$

- If z is a NaN, then return an element of $\text{nans}_N\{z\}$.
- Else if z is an infinity, then return z .
- Else if z is a zero, then return z .
- Else if z is greater than 0 but smaller than 1, then return positive zero.
- Else if z is smaller than 0 but greater than -1 , then return negative zero.
- Else return the integral value with the same sign as z and the largest magnitude that is not larger than the magnitude of z .

$$\begin{aligned}
 \text{ftrunc}_N(\pm\text{nan}(n)) &= \text{nans}_N\{\pm\text{nan}(n)\} \\
 \text{ftrunc}_N(\pm\infty) &= \pm\infty \\
 \text{ftrunc}_N(\pm 0) &= \pm 0 \\
 \text{ftrunc}_N(+q) &= +0 && (\text{if } 0 < +q < 1) \\
 \text{ftrunc}_N(-q) &= -0 && (\text{if } -1 < -q < 0) \\
 \text{ftrunc}_N(\pm q) &= \text{float}_N(\pm i) && (\text{if } +q - 1 < i \leq +q)
 \end{aligned}$$

$\text{fnearest}_N(z)$

- If z is a NaN, then return an element of $\text{nans}_N\{z\}$.
- Else if z is an infinity, then return z .
- Else if z is a zero, then return z .
- Else if z is greater than 0 but smaller than or equal to 0.5, then return positive zero.
- Else if z is smaller than 0 but greater than or equal to -0.5 , then return negative zero.
- Else return the integral value that is nearest to z ; if two values are equally near, return the even one.

$$\begin{aligned}
 \text{fnearest}_N(\pm\text{nan}(n)) &= \text{nans}_N\{\pm\text{nan}(n)\} \\
 \text{fnearest}_N(\pm\infty) &= \pm\infty \\
 \text{fnearest}_N(\pm 0) &= \pm 0 \\
 \text{fnearest}_N(+q) &= +0 && (\text{if } 0 < +q \leq 0.5) \\
 \text{fnearest}_N(-q) &= -0 && (\text{if } -0.5 \leq -q < 0) \\
 \text{fnearest}_N(\pm q) &= \text{float}_N(\pm i) && (\text{if } |i - q| < 0.5) \\
 \text{fnearest}_N(\pm q) &= \text{float}_N(\pm i) && (\text{if } |i - q| = 0.5 \wedge i \text{ even})
 \end{aligned}$$

$\text{feq}_N(z_1, z_2)$

- If either z_1 or z_2 is a NaN, then return 0.
- Else if both z_1 and z_2 are zeroes, then return 1.
- Else if both z_1 and z_2 are the same value, then return 1.
- Else return 0.

$$\begin{aligned}
 \text{feq}_N(\pm\text{nan}(n), z_2) &= 0 \\
 \text{feq}_N(z_1, \pm\text{nan}(n)) &= 0 \\
 \text{feq}_N(\pm 0, \mp 0) &= 1 \\
 \text{feq}_N(z_1, z_2) &= \text{bool}(z_1 = z_2)
 \end{aligned}$$

$\text{fneq}_N(z_1, z_2)$

- If either z_1 or z_2 is a NaN, then return 1.
- Else if both z_1 and z_2 are zeroes, then return 0.
- Else if both z_1 and z_2 are the same value, then return 0.
- Else return 1.

$$\begin{aligned}
\text{fne}_N(\pm\text{nan}(n), z_2) &= 1 \\
\text{fne}_N(z_1, \pm\text{nan}(n)) &= 1 \\
\text{fne}_N(\pm 0, \mp 0) &= 0 \\
\text{fne}_N(z_1, z_2) &= \text{bool}(z_1 \neq z_2)
\end{aligned}$$

$\text{flt}_N(z_1, z_2)$

- If either z_1 or z_2 is a NaN, then return 0.
- Else if z_1 and z_2 are the same value, then return 0.
- Else if z_1 is positive infinity, then return 0.
- Else if z_1 is negative infinity, then return 1.
- Else if z_2 is positive infinity, then return 1.
- Else if z_2 is negative infinity, then return 0.
- Else if both z_1 and z_2 are zeroes, then return 0.
- Else if z_1 is smaller than z_2 , then return 1.
- Else return 0.

$$\begin{aligned}
\text{flt}_N(\pm\text{nan}(n), z_2) &= 0 \\
\text{flt}_N(z_1, \pm\text{nan}(n)) &= 0 \\
\text{flt}_N(z, z) &= 0 \\
\text{flt}_N(+\infty, z_2) &= 0 \\
\text{flt}_N(-\infty, z_2) &= 1 \\
\text{flt}_N(z_1, +\infty) &= 1 \\
\text{flt}_N(z_1, -\infty) &= 0 \\
\text{flt}_N(\pm 0, \mp 0) &= 0 \\
\text{flt}_N(z_1, z_2) &= \text{bool}(z_1 < z_2)
\end{aligned}$$

$\text{fgt}_N(z_1, z_2)$

- If either z_1 or z_2 is a NaN, then return 0.
- Else if z_1 and z_2 are the same value, then return 0.
- Else if z_1 is positive infinity, then return 1.
- Else if z_1 is negative infinity, then return 0.
- Else if z_2 is positive infinity, then return 0.
- Else if z_2 is negative infinity, then return 1.
- Else if both z_1 and z_2 are zeroes, then return 0.
- Else if z_1 is larger than z_2 , then return 1.
- Else return 0.

$$\begin{aligned}
\text{fgt}_N(\pm\text{nan}(n), z_2) &= 0 \\
\text{fgt}_N(z_1, \pm\text{nan}(n)) &= 0 \\
\text{fgt}_N(z, z) &= 0 \\
\text{fgt}_N(+\infty, z_2) &= 1 \\
\text{fgt}_N(-\infty, z_2) &= 0 \\
\text{fgt}_N(z_1, +\infty) &= 0 \\
\text{fgt}_N(z_1, -\infty) &= 1 \\
\text{fgt}_N(\pm 0, \mp 0) &= 0 \\
\text{fgt}_N(z_1, z_2) &= \text{bool}(z_1 > z_2)
\end{aligned}$$

$\text{fle}_N(z_1, z_2)$

- If either z_1 or z_2 is a NaN, then return 0.
- Else if z_1 and z_2 are the same value, then return 1.
- Else if z_1 is positive infinity, then return 0.
- Else if z_1 is negative infinity, then return 1.
- Else if z_2 is positive infinity, then return 1.
- Else if z_2 is negative infinity, then return 0.
- Else if both z_1 and z_2 are zeroes, then return 1.
- Else if z_1 is smaller than or equal to z_2 , then return 1.
- Else return 0.

$$\begin{aligned}
 \text{fle}_N(\pm\text{nan}(n), z_2) &= 0 \\
 \text{fle}_N(z_1, \pm\text{nan}(n)) &= 0 \\
 \text{fle}_N(z, z) &= 1 \\
 \text{fle}_N(+\infty, z_2) &= 0 \\
 \text{fle}_N(-\infty, z_2) &= 1 \\
 \text{fle}_N(z_1, +\infty) &= 1 \\
 \text{fle}_N(z_1, -\infty) &= 0 \\
 \text{fle}_N(\pm 0, \mp 0) &= 1 \\
 \text{fle}_N(z_1, z_2) &= \text{bool}(z_1 \leq z_2)
 \end{aligned}$$

$\text{fge}_N(z_1, z_2)$

- If either z_1 or z_2 is a NaN, then return 0.
- Else if z_1 and z_2 are the same value, then return 1.
- Else if z_1 is positive infinity, then return 1.
- Else if z_1 is negative infinity, then return 0.
- Else if z_2 is positive infinity, then return 0.
- Else if z_2 is negative infinity, then return 1.
- Else if both z_1 and z_2 are zeroes, then return 1.
- Else if z_1 is larger than or equal to z_2 , then return 1.
- Else return 0.

$$\begin{aligned}
 \text{fge}_N(\pm\text{nan}(n), z_2) &= 0 \\
 \text{fge}_N(z_1, \pm\text{nan}(n)) &= 0 \\
 \text{fge}_N(z, z) &= 1 \\
 \text{fge}_N(+\infty, z_2) &= 1 \\
 \text{fge}_N(-\infty, z_2) &= 0 \\
 \text{fge}_N(z_1, +\infty) &= 0 \\
 \text{fge}_N(z_1, -\infty) &= 1 \\
 \text{fge}_N(\pm 0, \mp 0) &= 1 \\
 \text{fge}_N(z_1, z_2) &= \text{bool}(z_1 \geq z_2)
 \end{aligned}$$

$\text{fpmin}_N(z_1, z_2)$

- If z_2 is less than z_1 then return z_2 .
- Else return z_1 .

$$\begin{aligned}
 \text{fpmin}_N(z_1, z_2) &= z_2 \quad (\text{if } \text{flt}_N(z_2, z_1) = 1) \\
 \text{fpmin}_N(z_1, z_2) &= z_1 \quad (\text{otherwise})
 \end{aligned}$$

$\text{fpm}_{\text{max}}^N(z_1, z_2)$

- If z_1 is less than z_2 then return z_2 .
- Else return z_1 .

$$\begin{aligned}\text{fpm}_{\text{max}}^N(z_1, z_2) &= z_2 && (\text{if } \text{flt}_N(z_1, z_2) = 1) \\ \text{fpm}_{\text{max}}^N(z_1, z_2) &= z_1 && (\text{otherwise})\end{aligned}$$

4.3.4 Conversions

 $\text{extend}^u_{M,N}(i)$

- Return i .

$$\text{extend}^u_{M,N}(i) = i$$

Note

In the abstract syntax, unsigned extension just reinterprets the same value.

 $\text{extend}^s_{M,N}(i)$

- Let j be the [signed interpretation](#) of i of size M .
- Return the two's complement of j relative to size N .

$$\text{extend}^s_{M,N}(i) = \text{signed}_N^{-1}(\text{signed}_M(i))$$

 $\text{wrap}_{M,N}(i)$

- Return i modulo 2^N .

$$\text{wrap}_{M,N}(i) = i \bmod 2^N$$

 $\text{trunc}^u_{M,N}(z)$

- If z is a NaN, then the result is undefined.
- Else if z is an infinity, then the result is undefined.
- Else if z is a number and $\text{trunc}(z)$ is a value within range of the target type, then return that value.
- Else the result is undefined.

$$\begin{aligned}\text{trunc}^u_{M,N}(\pm \text{nan}(n)) &= \{\} \\ \text{trunc}^u_{M,N}(\pm \infty) &= \{\} \\ \text{trunc}^u_{M,N}(\pm q) &= \text{trunc}(\pm q) && (\text{if } -1 < \text{trunc}(\pm q) < 2^N) \\ \text{trunc}^u_{M,N}(\pm q) &= \{\} && (\text{otherwise})\end{aligned}$$

Note

This operator is [partial](#). It is not defined for NaNs, infinities, or values for which the result is out of range.

 $\text{trunc}^s_{M,N}(z)$

- If z is a NaN, then the result is undefined.
- Else if z is an infinity, then the result is undefined.
- If z is a number and $\text{trunc}(z)$ is a value within range of the target type, then return that value.
- Else the result is undefined.

$$\begin{aligned}
\text{trunc}_{M,N}^s(\pm\text{nan}(n)) &= \{\} \\
\text{trunc}_{M,N}^s(\pm\infty) &= \{\} \\
\text{trunc}_{M,N}^s(\pm q) &= \text{trunc}(\pm q) && (\text{if } -2^{N-1} - 1 < \text{trunc}(\pm q) < 2^{N-1}) \\
\text{trunc}_{M,N}^s(\pm q) &= \{\} && (\text{otherwise})
\end{aligned}$$

Note

This operator is **partial**. It is not defined for NaNs, infinities, or values for which the result is out of range.

$\text{trunc_sat_u}_{M,N}(z)$

- If z is a NaN, then return 0.
- Else if z is negative infinity, then return 0.
- Else if z is positive infinity, then return $2^N - 1$.
- Else, return $\text{sat_u}_N(\text{trunc}(z))$.

$$\begin{aligned}
\text{trunc_sat_u}_{M,N}(\pm\text{nan}(n)) &= 0 \\
\text{trunc_sat_u}_{M,N}(-\infty) &= 0 \\
\text{trunc_sat_u}_{M,N}(+\infty) &= 2^N - 1 \\
\text{trunc_sat_u}_{M,N}(z) &= \text{sat_u}_N(\text{trunc}(z))
\end{aligned}$$

$\text{trunc_sat_s}_{M,N}(z)$

- If z is a NaN, then return 0.
- Else if z is negative infinity, then return -2^{N-1} .
- Else if z is positive infinity, then return $2^{N-1} - 1$.
- Else, return the value whose signed interpretation is $\text{sat_s}_N(\text{trunc}(z))$.

$$\begin{aligned}
\text{trunc_sat_s}_{M,N}(\pm\text{nan}(n)) &= 0 \\
\text{trunc_sat_s}_{M,N}(-\infty) &= -2^{N-1} \\
\text{trunc_sat_s}_{M,N}(+\infty) &= 2^{N-1} - 1 \\
\text{trunc_sat_s}_{M,N}(z) &= \text{signed}_N^{-1}(\text{sat_s}_N(\text{trunc}(z)))
\end{aligned}$$

$\text{promote}_{M,N}(z)$

- If z is a **canonical NaN**, then return an element of $\text{nans}_N\{\}$ (i.e., a canonical NaN of size N).
- Else if z is a NaN, then return an element of $\text{nans}_N\{\pm\text{nan}(1)\}$ (i.e., any **arithmetic NaN** of size N).
- Else, return z .

$$\begin{aligned}
\text{promote}_{M,N}(\pm\text{nan}(n)) &= \text{nans}_N\{\} && (\text{if } n = \text{canon}_N) \\
\text{promote}_{M,N}(\pm\text{nan}(n)) &= \text{nans}_N\{+\text{nan}(1)\} && (\text{otherwise}) \\
\text{promote}_{M,N}(z) &= z
\end{aligned}$$

$\text{demote}_{M,N}(z)$

- If z is a **canonical NaN**, then return an element of $\text{nans}_N\{\}$ (i.e., a canonical NaN of size N).
- Else if z is a NaN, then return an element of $\text{nans}_N\{\pm\text{nan}(1)\}$ (i.e., any NaN of size N).
- Else if z is an infinity, then return that infinity.
- Else if z is a zero, then return that zero.
- Else, return $\text{float}_N(z)$.

$$\begin{aligned}
 \text{demote}_{M,N}(\pm \text{nan}(n)) &= \text{nan}_N\{\} && (\text{if } n = \text{canon}_N) \\
 \text{demote}_{M,N}(\pm \text{nan}(n)) &= \text{nan}_N\{+\text{nan}(1)\} && (\text{otherwise}) \\
 \text{demote}_{M,N}(\pm \infty) &= \pm \infty \\
 \text{demote}_{M,N}(\pm 0) &= \pm 0 \\
 \text{demote}_{M,N}(\pm q) &= \text{float}_N(\pm q)
 \end{aligned}$$

$\text{convert}^u_{M,N}(i)$

- Return $\text{float}_N(i)$.

$$\text{convert}^u_{M,N}(i) = \text{float}_N(i)$$

$\text{convert}^s_{M,N}(i)$

- Let j be the signed interpretation of i .
- Return $\text{float}_N(j)$.

$$\text{convert}^s_{M,N}(i) = \text{float}_N(\text{signed}_M(i))$$

$\text{reinterpret}_{t_1,t_2}(c)$

- Let d^* be the bit sequence $\text{bits}_{t_1}(c)$.
- Return the constant c' for which $\text{bits}_{t_2}(c') = d^*$.

$$\text{reinterpret}_{t_1,t_2}(c) = \text{bits}_{t_2}^{-1}(\text{bits}_{t_1}(c))$$

$\text{narrow}^s_{M,N}(i)$

- Let j be the signed interpretation of i of size M .
- Return the value whose signed interpretation is $\text{sat}_{s_N}(j)$.

$$\text{narrow}^s_{M,N}(i) = \text{signed}_N^{-1}(\text{sat}_{s_N}(\text{signed}_M(i)))$$

$\text{narrow}^u_{M,N}(i)$

- Let j be the signed interpretation of i of size M .
- Return $\text{sat}_{u_N}(j)$.

$$\text{narrow}^u_{M,N}(i) = \text{sat}_{u_N}(\text{signed}_M(i))$$

4.3.5 Vector Operations

Most vector operations are performed by applying numeric operations lanewise. However, some operators consider multiple lanes at once.

$\text{ivbitmask}_N(i^m)$

1. For each i_k in i^m , let b_k be the result of computing $\text{ilt}_{s_N}(i, 0)$.
2. Let b^m be the concatenation of all b_k .
3. Return the result of computing $\text{ibits}_{32}^{-1}((0)^{32-m} b^m)$.

$$\text{ivbitmask}_N(i^m) = \text{ibits}_{32}^{-1}((0)^{32-m} \text{ilt}_{s_N}(i, 0)^m)$$

$\text{ivswizzle}(i^n, j^n)$

1. For each j_k in j^n , let r_k be the value $\text{ivswizzle_lane}(i^n, j_k)$.
2. Let r^n be the concatenation of all r_k .
3. Return r^n .

$$\text{ivswizzle}(i^n, j^n) = \text{ivswizzle_lane}(i^n, j)^n$$

where:

$$\begin{aligned} \text{ivswizzle_lane}(i^n, j) &= i^n[j] && \text{(if } j < n) \\ \text{ivswizzle_lane}(i^n, j) &= 0 && \text{(otherwise)} \end{aligned}$$

$\text{ivshuffle}(j^n, i_1^n, i_2^n)$

1. Let i^* be the concatenation of i_1^n and i_2^n .
2. For each j_k in j^n , let r_k be $i^*[j_k]$.
3. Let r^n be the concatenation of all r_k .
4. Return r^n .

$$\text{ivshuffle}(j^n, i_1^n, i_2^n) = ((i_1^n \ i_2^n)[j])^n \quad \text{(if } (j < 2 \cdot n)^n)$$

$\text{ivadd_pairwise}_N(i^{2m})$

1. Let $(i_1 \ i_2)^m$ be i^{2m} , decomposed into pairwise elements.
2. For each i_{1k} in i_1^m and corresponding i_{2k} in i_2^m , let r_k be $\text{iadd}_N(i_{1k}, i_{2k})$.
3. Let r^m be the concatenation of all r_k .
4. Return r^m .

$$\text{ivadd_pairwise}_N(i^{2m}) = (\text{iadd}_N(i_1, i_2))^m \quad \text{(if } i^{2m} = (i_1 \ i_2)^m)$$

$\text{ivmul}_N(i_1^m, i_2^m)$

1. For each i_{1k} in i_1^m and corresponding i_{2k} in i_2^m , let r_k be $\text{imul}_N(i_{1k}, i_{2k})$.
2. Let r^m be the concatenation of all r_k .
3. Return r^m .

$$\text{ivmul}_N(i_1^m, i_2^m) = (\text{imul}_N(i_1, i_2))^m$$

$\text{ivdot}_N(i_1^{2m}, i_2^{2m})$

1. For each i_{1k} in i_1^{2m} and corresponding i_{2k} in i_2^{2m} , let j_k be $\text{imul}_N(i_{1k}, i_{2k})$.
2. Let j^{2m} be the concatenation of all j_k .
3. Let $(j_1 \ j_2)^m$ be j^{2m} , decomposed into pairwise elements.
4. For each i_{1k} in i_1^m and corresponding i_{2k} in i_2^m , let r_k be $\text{iadd}_N(i_{1k}, i_{2k})$.
5. Let r^m be the concatenation of all r_k .
6. Return r^m .

$$\text{ivdot}_N(i_1^{2m}, i_2^{2m}) = (\text{iadd}_N(j_1, j_2))^m \quad \text{(if } (\text{imul}_N(i_1, i_2))^{2m} = (j_1 \ j_2)^m)$$

$\text{ivdotsat}_N(i_1^m, i_2^m)$

1. For each i_{1k} in i_1^m and corresponding i_{2k} in i_2^m , let j_k be $\text{imul}_N(i_{1k}, i_{2k})$.
2. Let j^{2m} be the concatenation of all j_k .
3. Let $(j_1 j_2)^m$ be j^{2m} , decomposed into pairwise elements.
4. For each i_{1k} in i_1^m and corresponding i_{2k} in i_2^m , let r_k be $\text{iadd_sat}_N(i_{1k}, i_{2k})$.
5. Let r^m be the concatenation of all r_k .
6. Return r^m .

$$\text{ivdotsat}_N(i_1^{2m}, i_2^{2m}) = (\text{iadd_sat}_N(j_1, j_2))^m \quad (\text{if } (\text{imul}_N(i_1, i_2))^{2m} = (j_1 j_2)^m)$$

The previous operators are lifted to operators on arguments of vector type by wrapping them in corresponding lane projections and injections and intermediate extension operations:

 $\text{vextunop}_{sh_1, sh_2}(c)$

$$\begin{aligned} \text{extadd_pairwise_sx}_{i_{N_1 \times M_1}, i_{N_2 \times M_2}}(c) &= \text{lanes}_{i_{N_2 \times M_2}}^{-1}(j^*) \quad (\text{if } i^* = \text{lanes}_{i_{N_1 \times M_1}}(c) \\ &\quad \wedge i'^* = \text{extend}_{N_1, N_2}^{sx}(i)^* \\ &\quad \wedge j^* = \text{ivadd_pairwise}_{N_2}(i'^*)) \end{aligned}$$

 $\text{vextbinop}_{sh_1, sh_2}(c_1, c_2)$

$$\begin{aligned} \text{vextbinop}_{i_{N_1 \times M_1}, i_{N_2 \times M_2}}(c_1, c_2) &= \text{lanes}_{i_{N_2 \times M_2}}^{-1}(j^*) \quad (\text{if } i_1^* = \text{lanes}_{i_{N_1 \times M_1}}(c_1)[h : k] \\ &\quad \wedge i_2^* = \text{lanes}_{i_{N_1 \times M_1}}(c_2)[h : k] \\ &\quad \wedge i_1'^* = \text{extend}_{N_1, N_2}^{sx}(i_1)^* \\ &\quad \wedge i_2'^* = \text{extend}_{N_1, N_2}^{sx}(i_2)^* \\ &\quad \wedge j^* = f_{N_2}(i_1'^*, i_2'^*)) \end{aligned}$$

where f , sx_1 , sx_2 , h , and k are instantiated as follows, depending on the operator:

vextbinop	f	sx_1	sx_2	h	k
extmul_low_sx	ivmul	sx	sx	0	M_2
extmul_high_sx	ivmul	sx	sx	M_2	M_2
dot_s	ivdot	s	s	0	M_1
relaxed_dot_s	ivdotsat	s	$\text{relaxed}(R_{\text{idot}})[s, u]$	0	M_1

Note

Relaxed operations and the parameter R_{idot} are introduced [below](#).

 $\text{vextternop}_{sh_1, sh_2}(c_1, c_2, c_3)$

$$\begin{aligned} \text{relaxed_dot_add_s}_{i_{N_1 \times M_1}, i_{N_2 \times M_2}}(c_1, c_2, c_3) &= c \quad (\text{if } N = 2 \cdot N_1 \\ &\quad \wedge M = 2 \cdot M_2 \\ &\quad \wedge c' = \text{relaxed_dot_s}_{i_{N_1 \times M_1}, i_{N \times M}}(c_1, c_2) \\ &\quad \wedge c'' = \text{extadd_pairwise_s}_{i_{N \times M}, i_{N_2 \times M_2}}(c') \\ &\quad \wedge c \in \text{add}_{i_{N_2 \times M_2}}(c'', c_3)) \end{aligned}$$

 $\text{narrow_sx}_{sh_1, sh_2}(c_1, c_2)$

$$\begin{aligned} \text{narrow_sx}_{i_{N_1 \times M_1}, i_{N_2 \times M_2}}(c_1, c_2) &= \text{lanes}_{i_{N_2 \times M_2}}^{-1}(j^*) \quad (\text{if } i_1^* = \text{lanes}_{i_{N_1 \times M_1}}(c_1) \\ &\quad \wedge i_2^* = \text{lanes}_{i_{N_1 \times M_1}}(c_2) \\ &\quad \wedge i_1'^* = \text{narrow}_{N_1, N_2}^{sx}(i_1)^* \\ &\quad \wedge i_2'^* = \text{narrow}_{N_1, N_2}^{sx}(i_2)^* \\ &\quad \wedge j^* = i_1'^* \oplus i_2'^*) \end{aligned}$$

$$vcvtop_half^?_zero^?_{sh_1, sh_2}(i)$$

$$vcvtop_half^?_zero^?_{t_1 \times M_1, t_2 \times M_2}(i) = j \quad (\text{if } condition \\ \wedge c^* = \text{lanes}_{t_1 \times M_1}(i)[h : k] \\ \wedge c'^{**} = \times(vcvtop_{|t_1|, |t_2|}(c)^* \oplus (0)^n) \\ \wedge j \in \text{lanes}_{t_2 \times M_2}^{-1}(c'^{**})^*)$$

where h , k , n , and $condition$ are instantiated as follows, depending on the operator:

$half^?$	$zero^?$	h	k	n	$condition$
ϵ	ϵ	0	M_1	0	$(M_1 = M_2)$
low	ϵ	0	M_2	0	$(M_1 = 2 \cdot M_2)$
high	ϵ	M_2	M_2	0	$(M_1 = 2 \cdot M_2)$
ϵ	zero	0	M_1	M_1	$(2 \cdot M_1 = M_2)$

while $\times\{x^*\}^N$ transforms a sequence of N sets of non-deterministic values into a set of non-deterministic sequences of N values by computing the set product:

$$\times(S_1 \dots S_N) = \{x_1 \dots x_N \mid x_1 \in S_1 \wedge \dots \wedge x_N \in S_N\}$$

4.3.6 Relaxed Operations

The result of *relaxed* operators are *implementation-dependent*, because the set of possible results may depend on properties of the host environment, such as its hardware. Technically, their behaviour is controlled by a set of *global parameters* to the semantics that an implementation can instantiate in different ways. These choices are fixed, that is, parameters are constant during the execution of any given program.

Every such parameter is an index into a sequence of possible sets of results and must be instantiated to a defined index. In the *deterministic profile*, every parameter is prescribed to be 0. This behaviour is expressed by the following auxiliary function, where R is a global parameter selecting one of the allowed outcomes:

$$[!DET] \quad \begin{aligned} \text{relaxed}(R)[A_0, \dots, A_n] &= A_R \\ \text{relaxed}(R)[A_0, \dots, A_n] &= A_0 \end{aligned}$$

Note

Each parameter can be thought of as inducing a family of operations that is fixed to one particular choice by an implementation. The fixed operation itself can still be non-deterministic or partial.

Implementations are expected to either choose the behaviour that is the most efficient on the underlying hardware, or the behaviour of the deterministic profile.

$$\text{frelaxed_madd}_N(z_1, z_2, z_3)$$

The implementation-specific behaviour of this operation is determined by the global parameter $R_{\text{fmadd}} \in \{0, 1\}$.

- Return $\text{relaxed}(R_{\text{fmadd}})[\text{fadd}_N(\text{fmul}_N(z_1, z_2), z_3), \text{fma}_N(z_1, z_2, z_3)]$.

$$\text{frelaxed_madd}_N(z_1, z_2, z_3) = \text{relaxed}(R_{\text{fmadd}})[\text{fadd}_N(\text{fmul}_N(z_1, z_2), z_3), \text{fma}_N(z_1, z_2, z_3)]$$

Note

Relaxed multiply-add allows for fused or unfused results, which leads to implementation-dependent rounding behaviour. In the *deterministic profile*, the unfused behaviour is used.

$\text{frelaxed_nmadd}_N(z_1, z_2, z_3)$

- Return $\text{frelaxed_madd}(-z_1, z_2, z_3)$.

$$\text{frelaxed_nmadd}_N(z_1, z_2, z_3) = \text{frelaxed_madd}_N(-z_1, z_2, z_3)$$

Note

This operation is implementation-dependent because frelaxed_madd is implementation-dependent.

$\text{frelaxed_min}_N(z_1, z_2)$

The implementation-specific behaviour of this operation is determined by the global parameter $R_{\text{fmin}} \in \{0, 1, 2, 3\}$.

- If z_1 is a NaN, then return $\text{relaxed}(R_{\text{fmin}})[\text{fmin}_N(z_1, z_2), \text{nan}(n), z_2, z_2]$.
- If z_2 is a NaN, then return $\text{relaxed}(R_{\text{fmin}})[\text{fmin}_N(z_1, z_2), z_1, \text{nan}(n), z_1]$.
- If both z_1 and z_2 are zeroes of opposite sign, then return $\text{relaxed}(R_{\text{fmin}})[\text{fmin}_N(z_1, z_2), \text{pm } 0, \text{mp } 0, -0]$.
- Return $\text{fmin}_N(z_1, z_2)$.

$$\begin{aligned} \text{frelaxed_min}_N(\pm \text{nan}(n), z_2) &= \text{relaxed}(R_{\text{fmin}})[\text{fmin}_N(\pm \text{nan}(n), z_2), \text{nan}(n), z_2, z_2] \\ \text{frelaxed_min}_N(z_1, \pm \text{nan}(n)) &= \text{relaxed}(R_{\text{fmin}})[\text{fmin}_N(z_1, \pm \text{nan}(n)), z_1, \text{nan}(n), z_1] \\ \text{frelaxed_min}_N(\pm 0, \mp 0) &= \text{relaxed}(R_{\text{fmin}})[\text{fmin}_N(\pm 0, \mp 0), \pm 0, \mp 0, -0] \\ \text{frelaxed_min}_N(z_1, z_2) &= \text{fmin}_N(z_1, z_2) \quad (\text{otherwise}) \end{aligned}$$

Note

Relaxed minimum is implementation-dependent for NaNs and for zeroes with different signs. In the [deterministic profile](#), it behaves like regular fmin .

$\text{frelaxed_max}_N(z_1, z_2)$

The implementation-specific behaviour of this operation is determined by the global parameter $R_{\text{fmax}} \in \{0, 1, 2, 3\}$.

- If z_1 is a NaN, then return $\text{relaxed}(R_{\text{fmax}})[\text{fmax}_N(z_1, z_2), \text{nan}(n), z_2, z_2]$.
- If z_2 is a NaN, then return $\text{relaxed}(R_{\text{fmax}})[\text{fmax}_N(z_1, z_2), z_1, \text{nan}(n), z_1]$.
- If both z_1 and z_2 are zeroes of opposite sign, then return $\text{relaxed}(R_{\text{fmax}})[\text{fmax}_N(z_1, z_2), \text{pm } 0, \text{mp } 0, +0]$.
- Return $\text{fmax}_N(z_1, z_2)$.

$$\begin{aligned} \text{frelaxed_max}_N(\pm \text{nan}(n), z_2) &= \text{relaxed}(R_{\text{fmax}})[\text{fmax}_N(\pm \text{nan}(n), z_2), \text{nan}(n), z_2, z_2] \\ \text{frelaxed_max}_N(z_1, \pm \text{nan}(n)) &= \text{relaxed}(R_{\text{fmax}})[\text{fmax}_N(z_1, \pm \text{nan}(n)), z_1, \text{nan}(n), z_1] \\ \text{frelaxed_max}_N(\pm 0, \mp 0) &= \text{relaxed}(R_{\text{fmax}})[\text{fmax}_N(\pm 0, \mp 0), \pm 0, \mp 0, +0] \\ \text{frelaxed_max}_N(z_1, z_2) &= \text{fmax}_N(z_1, z_2) \quad (\text{otherwise}) \end{aligned}$$

Note

Relaxed maximum is implementation-dependent for NaNs and for zeroes with different signs. In the [deterministic profile](#), it behaves like regular fmax .

$\text{irelaxed_q15mulr_s}_N(i_1, i_2)$

The implementation-specific behaviour of this operation is determined by the global parameter $R_{\text{iq15mulr}} \in \{0, 1\}$.

- If both i_1 and i_2 equal $(\text{signed}_N^{-1}(-2^{N-1}))$, then return $\text{relaxed}(R_{\text{iq15mulr}})[2^{N-1} - 1, \text{signed}_N^{-1}(-2^{N-1})]$.
- Return $\text{iq15mulrsat_s}(i_1, i_2)$

$$\begin{aligned} \text{irelaxed_q15mulr_s}_N(\text{signed}_N^{-1}(-2^{N-1}), \text{signed}_N^{-1}(-2^{N-1})) &= \text{relaxed}(R_{\text{iq15mulr}})[2^{N-1} - 1, \text{signed}_N^{-1}(-2^{N-1})] \\ \text{irelaxed_q15mulr_s}_N(i_1, i_2) &= \text{iq15mulrsat_s}(i_1, i_2) \end{aligned}$$

Note

Relaxed Q15 multiplication is implementation-dependent when the result overflows. In the [deterministic profile](#), it behaves like regular `iq15mulrsat_s`.

$\text{relaxed_trunc}_{M,N}^u(z)$

The implementation-specific behaviour of this operation is determined by the global parameter $R_{\text{trunc_u}} \in \{0, 1\}$.

- If z is normal or subnormal and $\text{trunc}(z)$ is non-negative and less than 2^N , then return $\text{trunc}_{M,N}^u(z)$.
- Else, return $\text{relaxed}(R_{\text{trunc_u}})[\text{trunc_sat_u}_{M,N}(z), \mathbf{R}]$.

$$\begin{aligned} \text{relaxed_trunc}_{M,N}^u(\pm q) &= \text{trunc}_{M,N}^u(\pm q) && (\text{if } 0 \leq \text{trunc}(\pm q) < 2^N) \\ \text{relaxed_trunc}_{M,N}^u(z) &= \text{relaxed}(R_{\text{trunc_u}})[\text{trunc_sat_u}_{M,N}(z), \mathbf{R}] && (\text{otherwise}) \end{aligned}$$

Note

Relaxed unsigned truncation is non-deterministic for NaNs and out-of-range values. In the [deterministic profile](#), it behaves like regular `trunc_sat_u`.

$\text{relaxed_trunc}_{M,N}^s(z)$

The implementation-specific behaviour of this operation is determined by the global parameter $R_{\text{trunc_s}} \in \{0, 1\}$.

- If z is normal or subnormal and $\text{trunc}(z)$ is greater than or equal to -2^{N-1} and less than 2^{N-1} , then return $\text{trunc}_{M,N}^s(z)$.
- Else, return $\text{relaxed}(R_{\text{trunc_s}})[\text{trunc_sat_s}_{M,N}(z), \mathbf{R}]$.

$$\begin{aligned} \text{relaxed_trunc}_{M,N}^s(\pm q) &= \text{trunc}_{M,N}^s(\pm q) && (\text{if } -2^{N-1} \leq \text{trunc}(\pm q) < 2^{N-1}) \\ \text{relaxed_trunc}_{M,N}^s(z) &= \text{relaxed}(R_{\text{trunc_s}})[\text{trunc_sat_s}_{M,N}(z), \mathbf{R}] && (\text{otherwise}) \end{aligned}$$

Note

Relaxed signed truncation is non-deterministic for NaNs and out-of-range values. In the [deterministic profile](#), it behaves like regular `trunc_sat_s`.

$\text{ivrelaxed_swizzle}(i^n, j^n)$

The implementation-specific behaviour of this operation is determined by the global parameter $R_{\text{swizzle}} \in \{0, 1\}$.

- For each j_k in j^n , let r_k be the value $\text{ivrelaxed_swizzle_lane}(i^n, j_k)$.
- Let r^n be the concatenation of all r_k .
- Return r^n .

$$\text{ivrelaxed_swizzle}(i^n, j^n) = \text{ivrelaxed_swizzle_lane}(i^n, j)^n$$

where:

$$\begin{aligned} \text{ivrelaxed_swizzle_lane}(i^n, j) &= i[j] && (\text{if } j < 16) \\ \text{ivrelaxed_swizzle_lane}(i^n, j) &= 0 && (\text{if } \text{signed}_8(j) < 0) \\ \text{ivrelaxed_swizzle_lane}(i^n, j) &= \text{relaxed}(R_{\text{swizzle}})[0, i^n[j \bmod n]] && (\text{otherwise}) \end{aligned}$$

Note

Relaxed swizzle is implementation-dependent if the signed interpretation of any of the 8-bit indices in j^n is larger than or equal to 16. In the [deterministic profile](#), it behaves like regular `ivswizzle`.

`relaxed_dot(i_1, i_2)`

The implementation-specific behaviour of this operation is determined by the global parameter $R_{\text{idot}} \in \{0, 1\}$. It also affects the behaviour of `relaxed_dot_add`.

Its definition is part of the definition of *vectorbinop* specified [above](#).

Note

Relaxed dot product is implementation-dependent when the second operand is negative in a signed interpretation. In the [deterministic profile](#), it behaves like signed dot product.

`irelaxed_laneselect $_N$ (i_1, i_2, i_3)`

The implementation-specific behaviour of this operation is determined by the global parameter $R_{\text{laneselect}} \in \{0, 1\}$.

- If i_3 is smaller than 2^{N-1} , then let i'_3 be the value 0, otherwise $2^N - 1$.
- Let i''_3 be `relaxed($R_{\text{laneselect}}$)[i_3, i'_3]`.
- Return `ibitselect $_N$ (i_1, i_2, i''_3)`.

$$\text{irelaxed_laneselect}_N(i_1, i_2, i_3) = \text{ibitselect}_N(i_1, i_2, \text{relaxed}(R_{\text{laneselect}})[i_3, \text{extend}^s_{1,N}(\text{ishr_u}_N(i_3, N - 1))])$$

Note

Relaxed lane selection is non-deterministic when the mask mixes set and cleared bits, since the value of the high bit may or may not be expanded to all bits. In the [deterministic profile](#), it behaves like `ibitselect`.

4.4 Types

Execution has to check and compare [types](#) in a few places, such as [executing](#) `call_indirect` or [instantiating modules](#).

It is an invariant of the semantics that all types occurring during execution are [closed](#).

Note

Runtime type checks generally involve types from multiple modules or types not defined by a module at all, such that any module-local [type indices](#) occurring inside them would not generally be meaningful.

4.4.1 Instantiation

Any form of **type** can be *instantiated* into a **closed** type inside a **module instance** by substituting each **type index** x occurring in it with the corresponding **defined type** $moduleinst.types[x]$.

$$clos_{moduleinst}(t) = t[dt^*] \text{ if } dt^* = moduleinst.types$$

Note

This is the runtime equivalent to **type closure**, which is applied at validation time.

4.5 Values

4.5.1 Value Typing

For the purpose of checking argument **values** against the parameter types of exported **functions**, values are classified by **value types**. The following auxiliary typing rules specify this typing relation relative to a **store** S in which possibly referenced **addresses** live.

Numeric Values

The **number value** $(nt.const\ c)$ is **valid** with the **number type** nt .

$$\frac{}{s \vdash nt.const\ c : nt}$$

Vector Values

The **vector value** $(vt.const\ c)$ is **valid** with the **vector type** vt .

$$\frac{}{s \vdash vt.const\ c : vt}$$

Null References

The **reference value** $(ref.null\ ht)$ is **valid** with the **reference type** $(ref\ null\ ht')$ if:

- The **heap type** ht' matches the **heap type** ht .

$$\frac{\{\} \vdash ht' \leq ht}{s \vdash ref.null\ ht : (ref\ null\ ht')}$$

Note

A null reference can be typed with any smaller type. In particular, that allows it to be typed with the least type in its respective hierarchy. That ensures that the value is compatible with any nullable type in that hierarchy.

Scalar References

The **reference value** $(ref.i31\ i)$ is **valid** with the **reference type** $(ref\ i31)$.

$$\frac{}{s \vdash ref.i31\ i : (ref\ i31)}$$

Structure References

The **reference value** $(ref.struct\ a)$ is **valid** with the **reference type** $(ref\ dt)$ if:

- The **structure instance** $s.structs[a]$ exists.
- The **defined type** $s.structs[a].type$ is of the form dt .

$$\frac{s.structs[a].type = dt}{s \vdash ref.struct\ a : (ref\ dt)}$$

Array References

The reference value (`ref.array a`) is valid with the reference type (`ref dt`) if:

- The array instance `s.arrays[a]` exists.
- The defined type `s.arrays[a].type` is of the form `dt`.

$$\frac{s.\text{arrays}[a].\text{type} = dt}{s \vdash \text{ref.array } a : (\text{ref } dt)}$$

Exception References

The reference value (`ref.exn a`) is valid with the reference type (`ref exn`) if:

- The exception instance `s.exns[a]` exists.

$$\frac{s.\text{exns}[a] = \text{exn}}{s \vdash \text{ref.exn } a : (\text{ref exn})}$$

Function References

The reference value (`ref.func a`) is valid with the reference type (`ref dt`) if:

- The function instance `s.funcs[a]` exists.
- The defined type `s.funcs[a].type` is of the form `dt`.

$$\frac{s.\text{funcs}[a].\text{type} = dt}{s \vdash \text{ref.func } a : (\text{ref } dt)}$$

Host References

The reference value (`ref.host a`) is valid with the reference type (`ref any`).

$$\overline{s \vdash \text{ref.host } a : (\text{ref any})}$$

Note

A bare host reference is considered internalized.

External References

The reference value (`ref.extern addrref`) is valid with the reference type (`ref extern`) if:

- The reference value `addrref` is valid with the reference type (`ref any`).

$$\frac{s \vdash \text{addrref} : (\text{ref any})}{s \vdash \text{ref.extern } \text{addrref} : (\text{ref extern})}$$

Subsumption

The reference value `ref` is valid with the reference type `rt` if:

- The reference value `ref` is valid with the reference type `rt'`.
- The reference type `rt'` matches the reference type `rt`.

$$\frac{s \vdash \text{ref} : rt' \quad \{\} \vdash rt' \leq rt}{s \vdash \text{ref} : rt}$$

4.5.2 External Typing

For the purpose of checking [external address](#) against [imports](#), such values are classified by [external types](#). The following auxiliary typing rules specify this typing relation relative to a [store](#) S in which the referenced instances live.

Functions

The [external address](#) (`func a`) is valid with the [external type](#) (`func $funcinst.type$`) if:

- The function instance $s.funcs[a]$ exists.
- The function instance $s.funcs[a]$ is of the form $funcinst$.

$$\frac{s.funcs[a] = funcinst}{s \vdash \text{func } a : \text{func } funcinst.type}$$

Tables

The [external address](#) (`table a`) is valid with the [external type](#) (`table $tableinst.type$`) if:

- The table instance $s.tables[a]$ exists.
- The table instance $s.tables[a]$ is of the form $tableinst$.

$$\frac{s.tables[a] = tableinst}{s \vdash \text{table } a : \text{table } tableinst.type}$$

Memories

The [external address](#) (`mem a`) is valid with the [external type](#) (`mem $meminst.type$`) if:

- The memory instance $s.mems[a]$ exists.
- The memory instance $s.mems[a]$ is of the form $meminst$.

$$\frac{s.mems[a] = meminst}{s \vdash \text{mem } a : \text{mem } meminst.type}$$

Globals

The [external address](#) (`global a`) is valid with the [external type](#) (`global $globalinst.type$`) if:

- The global instance $s.globals[a]$ exists.
- The global instance $s.globals[a]$ is of the form $globalinst$.

$$\frac{s.globals[a] = globalinst}{s \vdash \text{global } a : \text{global } globalinst.type}$$

Tags

The [external address](#) (`tag a`) is valid with the [external type](#) (`tag $taginst.type$`) if:

- The tag instance $s.tags[a]$ exists.
- The tag instance $s.tags[a]$ is of the form $taginst$.

$$\frac{s.tags[a] = taginst}{s \vdash \text{tag } a : \text{tag } taginst.type}$$

Subsumption

The external address *externaddr* is valid with the external type *xt* if:

- The external address *externaddr* is valid with the external type *xt'*.
- The external type *xt'* matches the external type *xt*.

$$\frac{s \vdash \text{externaddr} : xt' \quad \{\} \vdash xt' \leq xt}{s \vdash \text{externaddr} : xt}$$

4.6 Instructions

WebAssembly computation is performed by executing individual instructions.

4.6.1 Parametric Instructions

nop

1. Do nothing.

$$\text{nop} \hookrightarrow \epsilon$$

unreachable

1. Trap.

$$\text{unreachable} \hookrightarrow \text{trap}$$

drop

1. Assert: Due to [validation](#), a value is on the top of the stack.
2. Pop the value *val* from the stack.

$$\text{val drop} \hookrightarrow \epsilon$$

select (t)?*

1. Assert: Due to [validation](#), a value of [number type](#) *i32* is on the top of the stack.
2. Pop the value (*i32.const c*) from the stack.
3. Assert: Due to [validation](#), a value is on the top of the stack.
4. Pop the value *val*₂ from the stack.
5. Assert: Due to [validation](#), a value is on the top of the stack.
6. Pop the value *val*₁ from the stack.
7. If *c* ≠ 0, then:
 - a. Push the value *val*₁ to the stack.
8. Else:
 - a. Push the value *val*₂ to the stack.

$$\begin{aligned} \text{val}_1 \text{ val}_2 \text{ (i32.const } c \text{) (select (t*)?) } &\hookrightarrow \text{val}_1 \quad \text{if } c \neq 0 \\ \text{val}_1 \text{ val}_2 \text{ (i32.const } c \text{) (select (t*)?) } &\hookrightarrow \text{val}_2 \quad \text{if } c = 0 \end{aligned}$$

Note

In future versions of WebAssembly, *select* may allow more than one value per choice.

4.6.2 Control Instructions

block $bt\ instr^*$

1. Let z be the current state.
2. Let $t_1^m \rightarrow_{localidx_0^*} t_2^n$ be the destructuring of $instrtype_z(bt)$.
3. Assert: Due to **validation**, $localidx_0^* = \epsilon$.
4. Assert: Due to **validation**, there are at least m values on the top of the stack.
5. Pop the values val^m from the stack.
6. Let L be the **label** whose arity is n and whose continuation is the end of the block.
7. Enter the block $val^m\ instr^*$ with the **label** L .

$$z; val^m (\text{block } bt\ instr^*) \hookrightarrow (\text{label}_n\{\epsilon\}\ val^m\ instr^*) \quad \text{if } instrtype_z(bt) = t_1^m \rightarrow t_2^n$$

loop $bt\ instr^*$

1. Let z be the current state.
2. Let $t_1^m \rightarrow_{localidx_0^*} t_2^n$ be the destructuring of $instrtype_z(bt)$.
3. Assert: Due to **validation**, $localidx_0^* = \epsilon$.
4. Assert: Due to **validation**, there are at least m values on the top of the stack.
5. Pop the values val^m from the stack.
6. Let L be the **label** whose arity is m and whose continuation is the start of the block.
7. Enter the block $val^m\ instr^*$ with the **label** L .

$$z; val^m (\text{loop } bt\ instr^*) \hookrightarrow (\text{label}_m\{\text{loop } bt\ instr^*\}\ val^m\ instr^*) \quad \text{if } instrtype_z(bt) = t_1^m \rightarrow t_2^n$$

if $bt\ instr_1^*\ instr_2^*$

1. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.
2. Pop the value $(i32.\text{const } c)$ from the stack.
3. If $c \neq 0$, then:
 - a. Execute the instruction $(\text{block } bt\ instr_1^*)$.
4. Else:
 - a. Execute the instruction $(\text{block } bt\ instr_2^*)$.

$$\begin{aligned} (i32.\text{const } c) (\text{if } bt\ instr_1^* \text{ else } instr_2^*) &\hookrightarrow (\text{block } bt\ instr_1^*) \quad \text{if } c \neq 0 \\ (i32.\text{const } c) (\text{if } bt\ instr_1^* \text{ else } instr_2^*) &\hookrightarrow (\text{block } bt\ instr_2^*) \quad \text{if } c = 0 \end{aligned}$$

br l

1. If the first non-value entry of the stack is a **label**, then:
 - a. Let L be the topmost **label**.
 - b. Let n be the arity of L .
 - c. If $l = 0$, then:
 - 1) Assert: Due to **validation**, there are at least n values on the top of the stack.
 - 2) Pop the values val^n from the stack.
 - 3) Pop all values val'^* from the top of the stack.
 - 4) Pop the **label** L from the stack.

- 5) Push the values val^n to the stack.
- 6) Jump to the continuation of L.
- d. Else:
 - 1) Pop all values val^* from the top of the stack.
 - 2) Pop the label L from the stack.
 - 3) Push the values val^* to the stack.
 - 4) Execute the instruction $(br\ l - 1)$.
2. Else:
 - a. Assert: Due to **validation**, the first non-value entry of the stack is a **handler**.
 - b. Pop all values val^* from the top of the stack.
 - c. Pop the handler H from the stack.
 - d. Push the values val^* to the stack.
 - e. Execute the instruction $(br\ l)$.

$$\begin{aligned}
 (\text{label}_n\{instr'^*\} val'^* val^n (br\ l) instr^*) &\hookrightarrow val^n instr'^* && \text{if } l = 0 \\
 (\text{label}_n\{instr'^*\} val'^* (br\ l) instr^*) &\hookrightarrow val^* (br\ l - 1) && \text{if } l > 0 \\
 (\text{handler}_n\{catch^*\} val^* (br\ l) instr^*) &\hookrightarrow val^* (br\ l)
 \end{aligned}$$

$br_if\ l$

1. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.
2. Pop the value $(i32.const\ c)$ from the stack.
3. If $c \neq 0$, then:
 - a. Execute the instruction $(br\ l)$.
4. Else:
 - a. Do nothing.

$$\begin{aligned}
 (i32.const\ c) (br_if\ l) &\hookrightarrow (br\ l) && \text{if } c \neq 0 \\
 (i32.const\ c) (br_if\ l) &\hookrightarrow \epsilon && \text{if } c = 0
 \end{aligned}$$

$br_table\ l^*\ l'$

1. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.
2. Pop the value $(i32.const\ i)$ from the stack.
3. If $i < |l^*|$, then:
 - a. Execute the instruction $(br\ l^*[i])$.
4. Else:
 - a. Execute the instruction $(br\ l')$.

$$\begin{aligned}
 (i32.const\ i) (br_table\ l^*\ l') &\hookrightarrow (br\ l^*[i]) && \text{if } i < |l^*| \\
 (i32.const\ i) (br_table\ l^*\ l') &\hookrightarrow (br\ l') && \text{if } i \geq |l^*|
 \end{aligned}$$

$br_on_null\ l$

1. Assert: Due to **validation**, a value is on the top of the stack.
2. Pop the value val from the stack.
3. If val is some **ref.null heapttype**, then:
 - a. Execute the instruction $(br\ l)$.

4. Else:

a. Push the value val to the stack.

$$\begin{aligned} val \text{ (br_on_null } l) &\hookrightarrow (\text{br } l) && \text{if } val = \text{ref.null } ht \\ val \text{ (br_on_null } l) &\hookrightarrow val && \text{otherwise} \end{aligned}$$

$\text{br_on_non_null } l$

1. Assert: Due to [validation](#), a value is on the top of the stack.

2. Pop the value val from the stack.

3. If val is some $\text{ref.null } heapttype$, then:

a. Do nothing.

4. Else:

a. Push the value val to the stack.

b. Execute the instruction $(\text{br } l)$.

$$\begin{aligned} val \text{ (br_on_non_null } l) &\hookrightarrow \epsilon && \text{if } val = \text{ref.null } ht \\ val \text{ (br_on_non_null } l) &\hookrightarrow val \text{ (br } l) && \text{otherwise} \end{aligned}$$

$\text{br_on_cast } l \text{ } rt_1 \text{ } rt_2$

1. Let f be the topmost frame.

2. Assert: Due to [validation](#), a [reference value](#) is on the top of the stack.

3. Pop the value ref from the stack.

4. Let rt be the type of ref .

5. Push the value ref to the stack.

6. If rt matches $\text{clos}_{f.\text{module}}(rt_2)$, then:

a. Execute the instruction $(\text{br } l)$.

7. Else:

a. Do nothing.

$$\begin{aligned} s; f; ref \text{ (br_on_cast } l \text{ } rt_1 \text{ } rt_2) &\hookrightarrow ref \text{ (br } l) && \text{if } s \vdash ref : rt \\ &&& \wedge \{\} \vdash rt \leq \text{clos}_{f.\text{module}}(rt_2) \\ s; f; ref \text{ (br_on_cast } l \text{ } rt_1 \text{ } rt_2) &\hookrightarrow ref && \text{otherwise} \end{aligned}$$

$\text{br_on_cast_fail } l \text{ } rt_1 \text{ } rt_2$

1. Let f be the topmost frame.

2. Assert: Due to [validation](#), a [reference value](#) is on the top of the stack.

3. Pop the value ref from the stack.

4. Let rt be the type of ref .

5. Push the value ref to the stack.

6. If rt matches $\text{clos}_{f.\text{module}}(rt_2)$, then:

a. Do nothing.

7. Else:

a. Execute the instruction $(\text{br } l)$.

$$\begin{aligned} s; f; ref \text{ (br_on_cast_fail } l \text{ } rt_1 \text{ } rt_2) &\hookrightarrow ref && \text{if } s \vdash ref : rt \\ &&& \wedge \{\} \vdash rt \leq \text{clos}_{f.\text{module}}(rt_2) \\ s; f; ref \text{ (br_on_cast_fail } l \text{ } rt_1 \text{ } rt_2) &\hookrightarrow ref \text{ (br } l) && \text{otherwise} \end{aligned}$$

return

1. If the first non-value entry of the stack is a **frame**, then:
 - a. Let f be the topmost **frame**.
 - b. Let n be the arity of f .
 - c. Assert: Due to **validation**, there are at least n values on the top of the stack.
 - d. Pop the values val^n from the stack.
 - e. Pop all values val'^* from the top of the stack.
 - f. Pop the **frame** F from the stack.
 - g. Push the values val^n to the stack.
2. Else if the first non-value entry of the stack is a **label**, then:
 - a. Pop all values val^* from the top of the stack.
 - b. Pop the **label** L from the stack.
 - c. Push the values val^* to the stack.
 - d. Execute the instruction **return**.
3. Else:
 - a. Assert: Due to **validation**, the first non-value entry of the stack is a **handler**.
 - b. Pop all values val^* from the top of the stack.
 - c. Pop the **handler** H from the stack.
 - d. Push the values val^* to the stack.
 - e. Execute the instruction **return**.

$$\begin{aligned}
 (\text{frame}_n\{f\} \ val'^* \ val^n \ \text{return} \ \text{instr}^*) &\hookrightarrow val^n \\
 (\text{label}_n\{\text{instr}'^*\} \ val^* \ \text{return} \ \text{instr}^*) &\hookrightarrow val^* \ \text{return} \\
 (\text{handler}_n\{\text{catch}^*\} \ val^* \ \text{return} \ \text{instr}^*) &\hookrightarrow val^* \ \text{return}
 \end{aligned}$$

call x

1. Let z be the current state.
2. Assert: Due to **validation**, $x < |z.\text{module}.\text{funcs}|$.
3. Let a be the **address** $z.\text{module}.\text{funcs}[x]$.
4. Assert: Due to **validation**, $a < |z.\text{funcs}|$.
5. Push the value $(\text{ref}.\text{func} \ a)$ to the stack.
6. Execute the instruction $(\text{call_ref} \ z.\text{funcs}[a].\text{type})$.

$$z; (\text{call} \ x) \hookrightarrow (\text{ref}.\text{func} \ a) (\text{call_ref} \ z.\text{funcs}[a].\text{type}) \quad \text{if } z.\text{module}.\text{funcs}[x] = a$$

call_ref x **Todo**

(*) Prose not spliced, for the prose merges the two cases of null and non-null references.

1. Assert: due to **validation**, a null or **function reference** is on the top of the stack.
2. Pop the reference value r from the stack.
3. If r is **ref.null ht** , then:

- a. Trap.
4. Assert: due to [validation](#), r is a [function reference](#).
5. Let $\text{ref.func } a$ be the reference r .
6. [Invoke](#) the function instance at address a .

$$z; (\text{ref.null } ht) (\text{call_ref } y) \hookrightarrow \text{trap}$$

Note

The formal rule for calling a non-null function reference is described [below](#).

`call_indirect x y`

1. Execute the instruction `(table.get x)`.
2. Execute the instruction `(ref.cast (ref null y))`.
3. Execute the instruction `(call_ref y)`.

$$(\text{call_indirect } x \ y) \hookrightarrow (\text{table.get } x) (\text{ref.cast (ref null } y)) (\text{call_ref } y)$$

`return_call x`

1. Let z be the current state.
2. Assert: Due to [validation](#), $x < |z.\text{module.funcs}|$.
3. Let a be the [address](#) $z.\text{module.funcs}[x]$.
4. Assert: Due to [validation](#), $a < |z.\text{funcs}|$.
5. Push the value `(ref.func a)` to the stack.
6. Execute the instruction `(return_call_ref $z.\text{funcs}[a].\text{type}$)`.

$$z; (\text{return_call } x) \hookrightarrow (\text{ref.func } a) (\text{return_call_ref } z.\text{funcs}[a].\text{type}) \quad \text{if } z.\text{module.funcs}[x] = a$$

`return_call_ref y`

1. Let z be the current state.
2. If the first non-value entry of the stack is a [label](#), then:
 - a. Pop all values val^* from the top of the stack.
 - b. Pop the [label](#) L from the stack.
 - c. Push the values val^* to the stack.
 - d. Execute the instruction `(return_call_ref y)`.
3. Else if the first non-value entry of the stack is a [handler](#), then:
 - a. Pop all values val^* from the top of the stack.
 - b. Pop the [handler](#) H from the stack.
 - c. Push the values val^* to the stack.
 - d. Execute the instruction `(return_call_ref y)`.
4. Else:
 - a. Assert: Due to [validation](#), the first non-value entry of the stack is a [frame](#).
 - b. Assert: Due to [validation](#), a value is on the top of the stack.

- c. Pop the value val'' from the stack.
- d. If val'' is some $ref.null\ heapytype$, then:
 - 1) Trap.
- e. Assert: Due to **validation**, val'' is some $ref.func\ funcaddr$.
- f. Let $(ref.func\ a)$ be the destructuring of val'' .
- g. Assert: Due to **validation**, $a < |z.funcs|$.
- h. Assert: Due to **validation**, the **expansion** of $z.funcs[a].type$ is some $func\ resulttype \rightarrow resulttype$.
- i. Let $(func\ t_1^n \rightarrow t_2^m)$ be the destructuring of the **expansion** of $z.funcs[a].type$.
- j. Assert: Due to **validation**, there are at least n values on the top of the stack.
- k. Pop the values val^n from the stack.
- l. Pop all values val'^* from the top of the stack.
- m. Pop the **frame** F from the stack.
- n. Push the values val^n to the stack.
- o. Push the value $(ref.func\ a)$ to the stack.
- p. Execute the instruction $(call_ref\ y)$.

$$\begin{aligned}
 z; (label_k \{instr'^*\} \ val'^* (return_call_ref\ y) \ instr'^*) &\hookrightarrow val'^* (return_call_ref\ y) \\
 z; (handler_k \{catch^*\} \ val'^* (return_call_ref\ y) \ instr'^*) &\hookrightarrow val'^* (return_call_ref\ y) \\
 z; (frame_k \{f\} \ val'^* (ref.null\ ht) (return_call_ref\ y) \ instr'^*) &\hookrightarrow trap \\
 z; (frame_k \{f\} \ val'^* \ val^n (ref.func\ a) (return_call_ref\ y) \ instr'^*) &\hookrightarrow val^n (ref.func\ a) (call_ref\ y) \\
 &\quad \text{if } z.funcs[a].type \approx func\ t_1^n \rightarrow t_2^m
 \end{aligned}$$

return_call_indirect $x\ y$

1. Execute the instruction $(table.get\ x)$.
2. Execute the instruction $(ref.cast\ (ref\ null\ y))$.
3. Execute the instruction $(return_call_ref\ y)$.

$$(return_call_indirect\ x\ y) \hookrightarrow (table.get\ x) (ref.cast\ (ref\ null\ y)) (return_call_ref\ y)$$

throw x

1. Let z be the current state.
2. Assert: Due to **validation**, $x < |z.tags|$.
3. Assert: Due to **validation**, the **expansion** of $z.tags[x].type$ is some $func\ resulttype \rightarrow resulttype$.
4. Let $(func\ t^n \rightarrow resulttype_0)$ be the destructuring of the **expansion** of $z.tags[x].type$.
5. Assert: Due to **validation**, $resulttype_0 = \epsilon$.
6. Let a be the length of $z.exns$.
7. Assert: Due to **validation**, there are at least n values on the top of the stack.
8. Pop the values val^n from the stack.
9. Let exn be the **exception instance** $\{tag\ z.tags[x],\ fields\ val^n\}$.
10. Append exn to $z.exns$.
11. Push the value $(ref.exn\ a)$ to the stack.
12. Execute the instruction **throw_ref**.

$$\begin{aligned}
z; \text{val}^n (\text{throw } x) \hookrightarrow z[\text{.exns} = \oplus \text{exn}]; (\text{ref.exn } a) \text{ throw_ref} \quad & \text{if } z.\text{tags}[x].\text{type} \approx \text{func } t^n \rightarrow \epsilon \\
& \wedge a = |z.\text{exns}| \\
& \wedge \text{exn} = \{\text{tag } z.\text{tags}[x], \text{fields } \text{val}^n\}
\end{aligned}$$

throw_ref

1. Let z be the current state.
2. Assert: Due to [validation](#), a value is on the top of the stack.
3. Pop the value val' from the stack.
4. If val' is some [ref.null heaptypes](#), then:
 - a. Trap.
5. If val' is some [ref.exn exnaddr](#), then:
 - a. Let $(\text{ref.exn } a)$ be the destructuring of val' .
 - b. Pop all values val^* from the top of the stack.
 - c. If $\text{val}^* \neq \epsilon$, then:
 - 1) Push the value $(\text{ref.exn } a)$ to the stack.
 - 2) Execute the instruction [throw_ref](#).
 - d. Else if the first non-value entry of the stack is a [label](#), then:
 - 1) Pop the [label](#) L from the stack.
 - 2) Push the value $(\text{ref.exn } a)$ to the stack.
 - 3) Execute the instruction [throw_ref](#).
 - e. Else:
 - 1) If the first non-value entry of the stack is a [frame](#), then:
 - a) Pop the [frame](#) F from the stack.
 - b) Push the value $(\text{ref.exn } a)$ to the stack.
 - c) Execute the instruction [throw_ref](#).
 - 2) Else if not the first non-value entry of the stack is a [handler](#), then:
 - a) Throw the exception val' as a result.
 - 3) Else:
 - a) Let H be the topmost [handler](#).
 - b) Let n be the arity of H .
 - c) Let catch''^* be the catch handler of H .
 - d) If $\text{catch}''^* = \epsilon$, then:
 1. Pop the [handler](#) H from the stack.
 2. Push the value $(\text{ref.exn } a)$ to the stack.
 3. Execute the instruction [throw_ref](#).
 - e) Else if $a \geq |z.\text{exns}|$, then:
 1. Let $\text{catch}_0 \text{ catch}''^*$ be catch''^* .
 2. If catch_0 is some [catch_all labelidx](#), then:
 - a. Let $(\text{catch_all } l)$ be the destructuring of catch_0 .
 - b. Pop the [handler](#) H from the stack.

- c. Execute the instruction (`br l`).
3. Else if `catch0` is not some `catch_all_ref labelidx`, then:
 - a. Let `catch catch'*` be `catch''*`.
 - b. Pop the `handler` H from the stack.
 - c. Let H be the `handler` whose arity is *n* and whose catch handler is `catch'*`.
 - d. Push the `handler` H.
 - e. Push the value (`ref.exn a`) to the stack.
 - f. Execute the instruction `throw_ref`.
4. Else:
 - a. Let (`catch_all_ref l`) be the destructuring of `catch0`.
 - b. Pop the `handler` H from the stack.
 - c. Push the value (`ref.exn a`) to the stack.
 - d. Execute the instruction (`br l`).
- f) Else:
 1. Let `val*` be `z.exns[a].fields`.
 2. Let `catch0 catch'*` be `catch''*`.
 3. If `catch0` is some `catch tagidx labelidx`, then:
 - a. Let (`catch x l`) be the destructuring of `catch0`.
 - b. If $x < |z.tags|$ and `z.exns[a].tag = z.tags[x]`, then:
 - 1) Pop the `handler` H from the stack.
 - 2) Push the values `val*` to the stack.
 - 3) Execute the instruction (`br l`).
 - c. Else:
 - 1) Let `catch catch'*` be `catch''*`.
 - 2) Pop the `handler` H from the stack.
 - 3) Let H be the `handler` whose arity is *n* and whose catch handler is `catch'*`.
 - 4) Push the `handler` H.
 - 5) Push the value (`ref.exn a`) to the stack.
 - 6) Execute the instruction `throw_ref`.
4. Else if `catch0` is some `catch_ref tagidx labelidx`, then:
 - a. Let (`catch_ref x l`) be the destructuring of `catch0`.
 - b. If $x \geq |z.tags|$ or `z.exns[a].tag \neq z.tags[x]`, then:
 - 1) Let `catch catch'*` be `catch''*`.
 - 2) Pop the `handler` H from the stack.
 - 3) Let H be the `handler` whose arity is *n* and whose catch handler is `catch'*`.
 - 4) Push the `handler` H.
 - 5) Push the value (`ref.exn a`) to the stack.
 - 6) Execute the instruction `throw_ref`.
 - c. Else:

- 1) Pop the **handler** H from the stack.
 - 2) Push the values val^* to the stack.
 - 3) Push the value $(ref.exn\ a)$ to the stack.
 - 4) Execute the instruction $(br\ l)$.
5. Else:
- a. If $catch_0$ is some **catch_all** $labelidx$, then:
 - 1) Let $(catch_all\ l)$ be the destructuring of $catch_0$.
 - 2) Pop the **handler** H from the stack.
 - 3) Execute the instruction $(br\ l)$.
 - b. Else if $catch_0$ is not some **catch_all_ref** $labelidx$, then:
 - 1) Let $catch\ catch'^*$ be $catch''^*$.
 - 2) Pop the **handler** H from the stack.
 - 3) Let H be the **handler** whose arity is n and whose catch handler is $catch'^*$.
 - 4) Push the **handler** H .
 - 5) Push the value $(ref.exn\ a)$ to the stack.
 - 6) Execute the instruction **throw_ref**.
 - c. Else:
 - 1) Let $(catch_all_ref\ l)$ be the destructuring of $catch_0$.
 - 2) Pop the **handler** H from the stack.
 - 3) Push the value $(ref.exn\ a)$ to the stack.
 - 4) Execute the instruction $(br\ l)$.
6. Else:
- a. Assert: Due to **validation**, not the first non-value entry of the stack is a **label**.
 - b. Assert: Due to **validation**, not the first non-value entry of the stack is a **frame**.
 - c. Assert: Due to **validation**, not the first non-value entry of the stack is a **handler**.
 - d. Throw the exception val' as a result.

$$\begin{array}{ll}

 \end{array}$$

try_table *bt* *catch*^{*} *instr*^{*}

1. Let z be the current state.
2. Let $t_1^m \rightarrow_{localidx_0^*} t_2^n$ be the destructuring of $instrtype_z(bt)$.
3. Assert: Due to **validation**, $localidx_0^* = \epsilon$.
4. Assert: Due to **validation**, there are at least m values on the top of the stack.
5. Pop the values val^m from the stack.
6. Let H be the **handler** whose arity is n and whose catch handler is *catch*^{*}.
7. Push the **handler** H .
8. Let L be the **label** whose arity is n and whose continuation is the end of the block.
9. Enter the block $val^m instr^*$ with the **label** L .

$z; val^m (try_table\ bt\ catch^*\ instr^*) \hookrightarrow (handler_n\{catch^*\}\ (label_n\{\epsilon\}\ val^m\ instr^*))$ if $instrtype_z(bt) = t_1^m \rightarrow t_2^n$

4.6.3 Blocks

The following auxiliary rules define the semantics of executing an **instruction sequence** that forms a **block**.

Entering *instr*^{*} with label *L* and values *val*^{*}

1. Push L to the stack.
2. Push the values val^* to the stack.
3. Jump to the start of the instruction sequence *instr*^{*}.

Note

No formal reduction rule is needed for entering an instruction sequence, because the label L is embedded in the **administrative instruction** that structured control instructions reduce to directly.

Exiting *instr*^{*} with label *L*

When the end of a block is reached without a jump, **exception**, or **trap** aborting it, then the following steps are performed.

1. Pop all values val^* from the top of the stack.
2. Assert: due to **validation**, the label L is now on the top of the stack.
3. Pop the label from the stack.
4. Push val^* back to the stack.
5. Jump to the position after the end of the **structured control instruction** associated with the label L .

$$(label_n\{instr^*\}\ val^*) \hookrightarrow val^*$$

Note

This semantics also applies to the instruction sequence contained in a loop instruction. Therefore, execution of a loop falls off the end, unless a backwards branch is performed explicitly.

4.6.4 Exception Handling

The following auxiliary rules define the semantics of entering and exiting try_table blocks.

Entering $instr^*$ with label L and exception handler H

1. Push H to the stack.
2. Push L onto the stack.
3. Jump to the start of the instruction sequence $instr^*$.

Note

No formal reduction rule is needed for entering an exception handler because it is an administrative instruction that the try_table instruction reduces to directly.

Exiting an exception handler

When the end of a try_table block is reached without a jump, exception, or trap, then the following steps are performed.

1. Let m be the number of values on the top of the stack.
2. Pop the values val^m from the stack.
3. Assert: due to validation, a handler and a label are now on the top of the stack.
4. Pop the label from the stack.
5. Pop the handler H from the stack.
6. Push val^m back to the stack.
7. Jump to the position after the end of the administrative instruction associated with the handler H .

$$(\text{handler}_n \{ \text{catch}^* \} \text{val}^*) \hookrightarrow \text{val}^*$$

4.6.5 Function Calls

The following auxiliary rules define the semantics of invoking a function instance through one of the call instructions and returning from it.

Invocation of function reference (ref.func a)

1. Assert: due to validation, $S.\text{funcs}[a]$ exists.
2. Let f be the function instance, $S.\text{funcs}[a]$.
3. Let $\text{func } [t_1^n] \rightarrow [t_2^m]$ be the composite type $\text{expand}(f.\text{type})$.
4. Let $\text{func } x \text{ local}^* \text{ instr}^*$ be the function $f.\text{code}$.
5. Assert: due to validation, n values are on the top of the stack.
6. Pop the values val^n from the stack.
7. Let F be the frame $\{\text{module } F.\text{module}, \text{locals } val^n (\text{default}_t)^*\}$.
8. Push the activation of f with arity m to the stack.
9. Let L be the label whose arity is m and whose continuation is the end of the function.
10. Enter the instruction sequence $instr^*$ with label L and no values.

$$\begin{aligned}
z; val^n (\text{ref.func } a) (\text{call_ref } y) &\hookrightarrow (\text{frame}_m\{f\} (\text{label}_m\{\epsilon\} \text{instr}^*)) \\
&\quad \text{if } z.\text{funcs}[a] = f \\
&\quad \wedge f.\text{type} \approx \text{func } t_1^n \rightarrow t_2^m \\
&\quad \wedge f.\text{code} = \text{func } x (\text{local } t)^* (\text{instr}^*) \\
&\quad \wedge f = \{\text{locals } val^n (\text{default}_t)^*, \text{module } f.\text{module}\}
\end{aligned}$$

Note

For non-defaultable types, the respective local is left uninitialized by these rules.

Returning from a function

When the end of a function is reached without a jump (including through `return`), or an `exception` or `trap` aborting it, then the following steps are performed.

1. Let F be the `current frame`.
2. Let n be the arity of the activation of F .
3. Assert: due to `validation`, there are n values on the top of the stack.
4. Pop the results val^n from the stack.
5. Assert: due to `validation`, the frame F is now on the top of the stack.
6. Pop the frame from the stack.
7. Push val^n back to the stack.
8. Jump to the instruction after the original call.

$$(\text{frame}_n\{f\} \text{val}^n) \hookrightarrow \text{val}^n$$

Host Functions

Invoking a `host function` has non-deterministic behavior. It may either terminate with a `trap`, an `exception`, or return regularly. However, in the latter case, it must consume and produce the right number and types of WebAssembly `values` on the stack, according to its `function type`.

A host function may also modify the `store`. However, all store modifications must result in an `extension` of the original store, i.e., they must only modify mutable contents and must not have instances removed. Furthermore, the resulting store must be `valid`, i.e., all data and code in it is well-typed.

$$\begin{aligned}
S; val^n (\text{invoke } a) &\hookrightarrow S'; \text{result} \\
&\quad (\text{if } S.\text{funcs}[a] = \{\text{type } \text{deftype}, \text{hostfunc } hf\} \\
&\quad \wedge \text{deftype} \approx \text{func } [t_1^n] \rightarrow [t_2^m] \\
&\quad \wedge (S'; \text{result}) \in hf(S; val^n)) \\
S; val^n (\text{invoke } a) &\hookrightarrow S; val^n (\text{invoke } a) \\
&\quad (\text{if } S.\text{funcs}[a] = \{\text{type } \text{deftype}, \text{hostfunc } hf\} \\
&\quad \wedge \text{deftype} \approx \text{func } [t_1^n] \rightarrow [t_2^m] \\
&\quad \wedge \perp \in hf(S; val^n))
\end{aligned}$$

Here, $hf(S; val^n)$ denotes the implementation-defined execution of host function hf in current store S with arguments val^n . It yields a set of possible outcomes, where each element is either a pair of a modified store S' and a `result` or the special value \perp indicating divergence. A host function is non-deterministic if there is at least one argument for which the set of outcomes is not singular.

For a WebAssembly implementation to be `sound` in the presence of host functions, every `host function instance` must be `valid`, which means that it adheres to suitable pre- and post-conditions: under a `valid store` S , and given arguments val^n matching the ascribed parameter types t_1^n , executing the host function must yield a non-empty set

of possible outcomes each of which is either divergence or consists of a valid store S' that is an [extension](#) of S and a result matching the ascribed return types t_2^m . All these notions are made precise in the [Appendix](#).

Note

A host function can call back into WebAssembly by [invoking](#) a function [exported](#) from a [module](#). However, the effects of any such call are subsumed by the non-deterministic behavior allowed for the host function.

4.6.6 Variable Instructions

`local.get x`

1. Let z be the current state.
2. Assert: Due to [validation](#), $z.\text{locals}[x]$ is defined.
3. Let val be $z.\text{locals}[x]$.
4. Push the value val to the stack.

$$z; (\text{local.get } x) \hookrightarrow val \quad \text{if } z.\text{locals}[x] = val$$

`local.set x`

1. Let z be the current state.
2. Assert: Due to [validation](#), a value is on the top of the stack.
3. Pop the value val from the stack.
4. Replace $z.\text{locals}[x]$ with val .

$$z; val (\text{local.set } x) \hookrightarrow z[\text{locals}[x] = val]; \epsilon$$

`local.tee x`

1. Assert: Due to [validation](#), a value is on the top of the stack.
2. Pop the value val from the stack.
3. Push the value val to the stack.
4. Push the value val to the stack.
5. Execute the instruction `(local.set x)`.

$$val (\text{local.tee } x) \hookrightarrow val \quad val (\text{local.set } x)$$

`global.get x`

1. Let z be the current state.
2. Let val be the [value](#) $z.\text{globals}[x].\text{value}$.
3. Push the value val to the stack.

$$z; (\text{global.get } x) \hookrightarrow val \quad \text{if } z.\text{globals}[x].\text{value} = val$$

`global.set x`

1. Let z be the current state.
2. Assert: Due to [validation](#), a value is on the top of the stack.
3. Pop the value val from the stack.
4. Replace $z.\text{globals}[x].\text{value}$ with val .

$$z; \text{val } (\text{global.set } x) \hookrightarrow z[\text{globals}[x].\text{value} = \text{val}]; \epsilon$$

4.6.7 Table Instructions

`table.get x`

1. Let z be the current state.
2. Assert: Due to [validation](#), a [number value](#) is on the top of the stack.
3. Pop the value ($\text{at.const } i$) from the stack.
4. If $i \geq |z.\text{tables}[x].\text{elem}|$, then:
 - a. Trap.
5. Push the value $z.\text{tables}[x].\text{elem}[i]$ to the stack.

$$\begin{aligned} z; (\text{at.const } i) (\text{table.get } x) &\hookrightarrow \text{trap} && \text{if } i \geq |z.\text{tables}[x].\text{elem}| \\ z; (\text{at.const } i) (\text{table.get } x) &\hookrightarrow z.\text{tables}[x].\text{elem}[i] && \text{if } i < |z.\text{tables}[x].\text{elem}| \end{aligned}$$

`table.set x`

1. Let z be the current state.
2. Assert: Due to [validation](#), a [reference value](#) is on the top of the stack.
3. Pop the value ref from the stack.
4. Assert: Due to [validation](#), a [number value](#) is on the top of the stack.
5. Pop the value ($\text{at.const } i$) from the stack.
6. If $i \geq |z.\text{tables}[x].\text{elem}|$, then:
 - a. Trap.
7. Replace $z.\text{tables}[x].\text{refs}[i]$ with ref .

$$\begin{aligned} z; (\text{at.const } i) \text{ref } (\text{table.set } x) &\hookrightarrow z; \text{trap} && \text{if } i \geq |z.\text{tables}[x].\text{elem}| \\ z; (\text{at.const } i) \text{ref } (\text{table.set } x) &\hookrightarrow z.\text{tables}[x].\text{elem}[i] = \text{ref}; \epsilon && \text{if } i < |z.\text{tables}[x].\text{elem}| \end{aligned}$$

`table.size x`

1. Let z be the current state.
2. Let $(\text{at } \text{lim } rt)$ be the destructuring of $z.\text{tables}[x].\text{type}$.
3. Let n be the length of $z.\text{tables}[x].\text{elem}$.
4. Push the value ($\text{at.const } n$) to the stack.

$$z; (\text{table.size } x) \hookrightarrow (\text{at.const } n) \quad \begin{aligned} &\text{if } |z.\text{tables}[x].\text{elem}| = n \\ &\wedge z.\text{tables}[x].\text{type} = \text{at } \text{lim } rt \end{aligned}$$

`table.grow x`

1. Let z be the current state.
2. Assert: Due to [validation](#), a [number value](#) is on the top of the stack.
3. Pop the value ($\text{at.const } n$) from the stack.
4. Assert: Due to [validation](#), a [reference value](#) is on the top of the stack.
5. Pop the value ref from the stack.
6. Either:

- a. Let ti be the table instance $\text{growtable}(z.\text{tables}[x], n, \text{ref})$.
 - b. Push the value $(\text{at.const } |z.\text{tables}[x].\text{elem}|)$ to the stack.
 - c. Replace $z.\text{tables}[x]$ with ti .
7. Or:
- a. Push the value $(\text{at.const signed}_{|at|}^{-1}(-1))$ to the stack.
- $$z; \text{ref } (\text{at.const } n) (\text{table.grow } x) \hookrightarrow z[\text{tables}[x] = ti]; (\text{at.const } |z.\text{tables}[x].\text{elem}|)$$
- $$\text{if } ti = \text{growtable}(z.\text{tables}[x], n, \text{ref})$$
- $$z; \text{ref } (\text{at.const } n) (\text{table.grow } x) \hookrightarrow z; (\text{at.const signed}_{|at|}^{-1}(-1))$$

Note

The `table.grow` instruction is non-deterministic. It may either succeed, returning the old table size sz , or fail, returning -1 . Failure *must* occur if the referenced table instance has a maximum size defined that would be exceeded. However, failure *can* occur in other cases as well. In practice, the choice depends on the `resources` available to the `embedder`.

`table.fill x`

1. Let z be the current state.
 2. Assert: Due to `validation`, a number value is on the top of the stack.
 3. Pop the value $(\text{at.const } n)$ from the stack.
 4. Assert: Due to `validation`, a value is on the top of the stack.
 5. Pop the value val from the stack.
 6. Assert: Due to `validation`, a value of number type at is on the top of the stack.
 7. Pop the value $(\text{numtype}_0.\text{const } i)$ from the stack.
 8. If $i + n > |z.\text{tables}[x].\text{elem}|$, then:
 - a. Trap.
 9. If $n = 0$, then:
 - a. Do nothing.
 10. Else:
 - a. Push the value $(\text{at.const } i)$ to the stack.
 - b. Push the value val to the stack.
 - c. Execute the instruction `(table.set x)`.
 - d. Push the value $(\text{at.const } i + 1)$ to the stack.
 - e. Push the value val to the stack.
 - f. Push the value $(\text{at.const } n - 1)$ to the stack.
 - g. Execute the instruction `(table.fill x)`.
- $$z; (\text{at.const } i) \text{ val } (\text{at.const } n) (\text{table.fill } x) \hookrightarrow \text{trap} \quad \text{if } i + n > |z.\text{tables}[x].\text{elem}|$$
- $$z; (\text{at.const } i) \text{ val } (\text{at.const } n) (\text{table.fill } x) \hookrightarrow \epsilon \quad \text{otherwise, if } n = 0$$
- $$z; (\text{at.const } i) \text{ val } (\text{at.const } n) (\text{table.fill } x) \hookrightarrow$$
- $$(\text{at.const } i) \text{ val } (\text{table.set } x) \quad \text{otherwise}$$
- $$(\text{at.const } i + 1) \text{ val } (\text{at.const } n - 1) (\text{table.fill } x)$$

`table.copy` x_1 x_2

1. Let z be the current state.
 2. Assert: Due to [validation](#), a [number value](#) is on the top of the stack.
 3. Pop the value ($at.const\ n$) from the stack.
 4. Assert: Due to [validation](#), a [number value](#) is on the top of the stack.
 5. Pop the value ($at_2.const\ i_2$) from the stack.
 6. Assert: Due to [validation](#), a [number value](#) is on the top of the stack.
 7. Pop the value ($at_1.const\ i_1$) from the stack.
 8. If $i_1 + n > |z.tables[x_1].elem|$, then:
 - a. Trap.
 9. If $i_2 + n > |z.tables[x_2].elem|$, then:
 - a. Trap.
 10. If $n = 0$, then:
 - a. Do nothing.
 11. Else:
 - a. If $i_1 \leq i_2$, then:
 - 1) Push the value ($at_1.const\ i_1$) to the stack.
 - 2) Push the value ($at_2.const\ i_2$) to the stack.
 - 3) Execute the instruction (`table.get` x_2).
 - 4) Execute the instruction (`table.set` x_1).
 - 5) Push the value ($at_1.const\ i_1 + 1$) to the stack.
 - 6) Push the value ($at_2.const\ i_2 + 1$) to the stack.
 - b. Else:
 - 1) Push the value ($at_1.const\ i_1 + n - 1$) to the stack.
 - 2) Push the value ($at_2.const\ i_2 + n - 1$) to the stack.
 - 3) Execute the instruction (`table.get` x_2).
 - 4) Execute the instruction (`table.set` x_1).
 - 5) Push the value ($at_1.const\ i_1$) to the stack.
 - 6) Push the value ($at_2.const\ i_2$) to the stack.
 - c. Push the value ($at.const\ n - 1$) to the stack.
 - d. Execute the instruction (`table.copy` x_1 x_2).
- $z; (at_1.const\ i_1) (at_2.const\ i_2) (at'.const\ n) (table.copy\ x_1\ x_2) \hookrightarrow \text{trap}$
 if $i_1 + n > |z.tables[x_1].elem| \vee i_2 + n > |z.tables[x_2].elem|$
 $z; (at_1.const\ i_1) (at_2.const\ i_2) (at'.const\ n) (table.copy\ x\ y) \hookrightarrow \epsilon$ otherwise, if $n = 0$
 $z; (at_1.const\ i_1) (at_2.const\ i_2) (at'.const\ n) (table.copy\ x\ y) \hookrightarrow$
 $(at_1.const\ i_1) (at_2.const\ i_2) (table.get\ y) (table.set\ x)$ otherwise, if $i_1 \leq i_2$
 $(at_1.const\ i_1 + 1) (at_2.const\ i_2 + 1) (at'.const\ n - 1) (table.copy\ x\ y)$
 $z; (at_1.const\ i_1) (at_2.const\ i_2) (at'.const\ n) (table.copy\ x\ y) \hookrightarrow$
 $(at_1.const\ i_1 + n - 1) (at_2.const\ i_2 + n - 1) (table.get\ y) (table.set\ x)$ otherwise
 $(at_1.const\ i_1) (at_2.const\ i_2) (at'.const\ n - 1) (table.copy\ x\ y)$

table.init $x\ y$

1. Let z be the current state.
 2. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.
 3. Pop the value (**i32.const n**) from the stack.
 4. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.
 5. Pop the value (**i32.const j**) from the stack.
 6. Assert: Due to **validation**, a **number value** is on the top of the stack.
 7. Pop the value (**at.const i**) from the stack.
 8. If $i + n > |z.tables[x].elem|$, then:
 - a. Trap.
 9. If $j + n > |z.elems[y].elem|$, then:
 - a. Trap.
 10. If $n = 0$, then:
 - a. Do nothing.
 11. Else:
 - a. Assert: Due to **validation**, $j < |z.elems[y].elem|$.
 - b. Push the value (**at.const i**) to the stack.
 - c. Push the value $z.elems[y].elem[j]$ to the stack.
 - d. Execute the instruction (**table.set x**).
 - e. Push the value (**at.const $i + 1$**) to the stack.
 - f. Push the value (**i32.const $j + 1$**) to the stack.
 - g. Push the value (**i32.const $n - 1$**) to the stack.
 - h. Execute the instruction (**table.init $x\ y$**).
- $$\begin{aligned}
 z; (\text{at.const } i) (\text{i32.const } j) (\text{i32.const } n) (\text{table.init } x\ y) &\hookrightarrow \text{trap} \\
 &\quad \text{if } i + n > |z.tables[x].elem| \vee j + n > |z.elems[y].elem| \\
 z; (\text{at.const } i) (\text{i32.const } j) (\text{i32.const } n) (\text{table.init } x\ y) &\hookrightarrow \epsilon \quad \text{otherwise, if } n = 0 \\
 z; (\text{at.const } i) (\text{i32.const } j) (\text{i32.const } n) (\text{table.init } x\ y) &\hookrightarrow \\
 &\quad (\text{at.const } i) z.elems[y].elem[j] (\text{table.set } x) \quad \text{otherwise} \\
 &\quad (\text{at.const } i + 1) (\text{i32.const } j + 1) (\text{i32.const } n - 1) (\text{table.init } x\ y)
 \end{aligned}$$

elem.drop x

1. Let z be the current state.
2. Replace $z.elems[x].refs$ with ϵ .

$$z; (\text{elem.drop } x) \hookrightarrow z[elems[x].elem = \epsilon]; \epsilon$$

4.6.8 Memory Instructions**Note**

The alignment **memarg.align** in load and store instructions does not affect the semantics. It is a hint that the offset ea at which the memory is accessed is intended to satisfy the property $ea \bmod 2^{\text{memarg.align}} = 0$. A WebAssembly implementation can use this hint to optimize for the intended use. Unaligned access violating

that property is still allowed and must succeed regardless of the annotation. However, it may be substantially slower on some hardware.

nt.loadloadop? *x ao*

1. Let z be the current state.
2. Assert: Due to validation, a **number value** is on the top of the stack.
3. Pop the value ($at.const\ i$) from the stack.
4. If *loadop?* is not defined, then:
 - a. If $i + ao.offset + |nt|/8 > |z.mems[x].bytes|$, then:
 - 1) Trap.
 - b. Let c be the result for which $bytes_{nt}(c) = z.mems[x].bytes[i + ao.offset : |nt|/8]$.
 - c. Push the value ($nt.const\ c$) to the stack.
5. Else:
 - a. Assert: Due to validation, nt is *iv*.
 - b. Let *loadop*₀ be *loadop?*.
 - c. Let n_sx be the destructuring of *loadop*₀.
 - d. If $i + ao.offset + n/8 > |z.mems[x].bytes|$, then:
 - 1) Trap.
 - e. Let c be the result for which $bytes_{in}(c) = z.mems[x].bytes[i + ao.offset : n/8]$.
 - f. Push the value ($nt.const\ extend_{n,|nt|}^{sx}(c)$) to the stack.

$$\begin{aligned}
 z; (at.const\ i) (nt.load\ x\ ao) &\hookrightarrow \text{trap} && \text{if } i + ao.offset + |nt|/8 > |z.mems[x].bytes| \\
 z; (at.const\ i) (nt.load\ x\ ao) &\hookrightarrow (nt.const\ c) && \text{if } bytes_{nt}(c) = z.mems[x].bytes[i + ao.offset : |nt|/8] \\
 z; (at.const\ i) (iv.loadn_sx\ x\ ao) &\hookrightarrow \text{trap} && \text{if } i + ao.offset + n/8 > |z.mems[x].bytes| \\
 z; (at.const\ i) (iv.loadn_sx\ x\ ao) &\hookrightarrow (iv.const\ extend_{n,|iv|}^{sx}(c)) && \text{if } bytes_{in}(c) = z.mems[x].bytes[i + ao.offset : n/8]
 \end{aligned}$$

v128.loadM×K_sx x ao

1. Let z be the current state.
2. Assert: Due to validation, a **number value** is on the top of the stack.
3. Pop the value ($at.const\ i$) from the stack.
4. If $i + ao.offset + M \cdot K/8 > |z.mems[x].bytes|$, then:
 - a. Trap.
5. Let j^K be the result for which $(bytes_{iM}(j^K) = z.mems[x].bytes[i + ao.offset + k \cdot M/8 : M/8])^{k < K}$.
6. Let *iv* be the result for which $N = M \cdot 2$.
7. Let c be $lanes_{iv \times K}^{-1}(extend_{M,N}^{sx}(j)^K)$.
8. Push the value ($v128.const\ c$) to the stack.

$$\begin{aligned}
 z; (at.const\ i) (v128.loadM \times K_sx\ x\ ao) &\hookrightarrow \text{trap} && \text{if } i + ao.offset + M \cdot K/8 > |z.mems[x].bytes| \\
 z; (at.const\ i) (v128.loadM \times K_sx\ x\ ao) &\hookrightarrow (v128.const\ c) && \text{if } (bytes_{iM}(j) = z.mems[x].bytes[i + ao.offset + k \cdot M/8 : M/8])^{k < K} \\
 &&& \wedge c = lanes_{iv \times K}^{-1}(extend_{M,N}^{sx}(j)^K) \wedge N = M \cdot 2
 \end{aligned}$$

v128.loadN_splat *x ao*

1. Let z be the current state.
2. Assert: Due to validation, a **number value** is on the top of the stack.
3. Pop the value ($at.const\ i$) from the stack.
4. If $i + ao.offset + N/8 > |z.mems[x].bytes|$, then:
 - a. Trap.
5. Let M be $128/N$.
6. Let i_N be the result for which $|i_N| = N$.
7. Let j be the result for which $bytes_{i_N}(j) = z.mems[x].bytes[i + ao.offset : N/8]$.
8. Let c be $lanes_{i_N \times M}^{-1}(j^M)$.
9. Push the value ($v128.const\ c$) to the stack.

$$\begin{aligned}
 z; (at.const\ i) (v128.loadN_splat\ x\ ao) &\hookrightarrow \text{trap} && \text{if } i + ao.offset + N/8 > |z.mems[x].bytes| \\
 z; (at.const\ i) (v128.loadN_splat\ x\ ao) &\hookrightarrow (v128.const\ c) && \begin{aligned} &\text{if } bytes_{i_N}(j) = z.mems[x].bytes[i + ao.offset : N/8] \\ &\wedge N = |i_N| \\ &\wedge M = 128/N \\ &\wedge c = lanes_{i_N \times M}^{-1}(j^M) \end{aligned}
 \end{aligned}$$
v128.loadN_zero *x ao*

1. Let z be the current state.
2. Assert: Due to validation, a **number value** is on the top of the stack.
3. Pop the value ($at.const\ i$) from the stack.
4. If $i + ao.offset + N/8 > |z.mems[x].bytes|$, then:
 - a. Trap.
5. Let j be the result for which $bytes_{i_N}(j) = z.mems[x].bytes[i + ao.offset : N/8]$.
6. Let c be $extend_{N,128}^u(j)$.
7. Push the value ($v128.const\ c$) to the stack.

$$\begin{aligned}
 z; (at.const\ i) (v128.loadN_zero\ x\ ao) &\hookrightarrow \text{trap} && \text{if } i + ao.offset + N/8 > |z.mems[x].bytes| \\
 z; (at.const\ i) (v128.loadN_zero\ x\ ao) &\hookrightarrow (v128.const\ c) && \begin{aligned} &\text{if } bytes_{i_N}(j) = z.mems[x].bytes[i + ao.offset : N/8] \\ &\wedge c = extend_{N,128}^u(j) \end{aligned}
 \end{aligned}$$
v128.loadN_lane *x ao j*

1. Let z be the current state.
2. Assert: Due to **validation**, a value of **vector type v128** is on the top of the stack.
3. Pop the value ($v128.const\ c_1$) from the stack.
4. Assert: Due to **validation**, a **number value** is on the top of the stack.
5. Pop the value ($at.const\ i$) from the stack.
6. If $i + ao.offset + N/8 > |z.mems[x].bytes|$, then:
 - a. Trap.
7. Let M be $|v128|/N$.
8. Let i_N be the result for which $|i_N| = N$.

9. Let k be the result for which $\text{bytes}_{iN}(k) = z.\text{mems}[x].\text{bytes}[i + ao.\text{offset} : N/8]$.
 10. Let c be $\text{lanes}_{iN \times M}^{-1}(\text{lanes}_{iN \times M}(c_1)[[j] = k])$.
 11. Push the value $(\text{v128.const } c)$ to the stack.
- $$\begin{aligned}
 z; (at.\text{const } i) (\text{v128.const } c_1) (\text{v128.loadN_lane } x \text{ } ao \text{ } j) &\hookrightarrow \text{trap} && \text{if } i + ao.\text{offset} + N/8 > |z.\text{mems}[x].\text{bytes}| \\
 z; (at.\text{const } i) (\text{v128.const } c_1) (\text{v128.loadN_lane } x \text{ } ao \text{ } j) &\hookrightarrow (\text{v128.const } c) && \begin{aligned} &\text{if } \text{bytes}_{iN}(k) = z.\text{mems}[x].\text{bytes}[i + ao.\text{offset} : N/8] \\ &\wedge N = |iN| \\ &\wedge M = |\text{v128}|/N \\ &\wedge c = \text{lanes}_{iN \times M}^{-1}(\text{lanes}_{iN \times M}(c_1)[[j] = k]) \end{aligned}
 \end{aligned}$$

nt.storestoreop? $x \text{ } ao$

1. Let z be the current state.
 2. Assert: Due to **validation**, a **number value** is on the top of the stack.
 3. Pop the value $(nt'.\text{const } c)$ from the stack.
 4. Assert: Due to **validation**, a value is on the top of the stack.
 5. Pop the value $(at.\text{const } i)$ from the stack.
 6. Assert: Due to **validation**, $nt = nt'$.
 7. If *storeop?* is not defined, then:
 - a. If $i + ao.\text{offset} + |nt'|/8 > |z.\text{mems}[x].\text{bytes}|$, then:
 - 1) Trap.
 - b. Let b^* be $\text{bytes}_{nt'}(c)$.
 - c. Replace $z.\text{mems}[x].\text{bytes}[i + ao.\text{offset} : |nt'|/8]$ with b^* .
 8. Else:
 - a. Assert: Due to **validation**, nt' is iN .
 - b. Let n be *storeop?*.
 - c. If $i + ao.\text{offset} + n/8 > |z.\text{mems}[x].\text{bytes}|$, then:
 - 1) Trap.
 - d. Let b^* be $\text{bytes}_{in}(\text{wrap}_{|nt'|,n}(c))$.
 - e. Replace $z.\text{mems}[x].\text{bytes}[i + ao.\text{offset} : n/8]$ with b^* .
- $$\begin{aligned}
 z; (at.\text{const } i) (nt.\text{const } c) (nt.\text{store } x \text{ } ao) &\hookrightarrow z; \text{trap} && \text{if } i + ao.\text{offset} + |nt|/8 > |z.\text{mems}[x].\text{bytes}| \\
 z; (at.\text{const } i) (nt.\text{const } c) (nt.\text{store } x \text{ } ao) &\hookrightarrow z[\text{mems}[x].\text{bytes}[i + ao.\text{offset} : |nt|/8] = b^*]; \epsilon && \text{if } b^* = \text{bytes}_{nt}(c) \\
 z; (at.\text{const } i) (iN.\text{const } c) (iN.\text{storeN } x \text{ } ao) &\hookrightarrow z; \text{trap} && \text{if } i + ao.\text{offset} + n/8 > |z.\text{mems}[x].\text{bytes}| \\
 z; (at.\text{const } i) (iN.\text{const } c) (iN.\text{storeN } x \text{ } ao) &\hookrightarrow z[\text{mems}[x].\text{bytes}[i + ao.\text{offset} : n/8] = b^*]; \epsilon && \text{if } b^* = \text{bytes}_{in}(\text{wrap}_{|iN|,n}(c)) \\
 z; (at.\text{const } i) (\text{v128.const } c) (\text{v128.store } x \text{ } ao) &\hookrightarrow z; \text{trap} && \text{if } i + ao.\text{offset} + |\text{v128}|/8 > |z.\text{mems}[x].\text{bytes}| \\
 z; (at.\text{const } i) (\text{v128.const } c) (\text{v128.store } x \text{ } ao) &\hookrightarrow z[\text{mems}[x].\text{bytes}[i + ao.\text{offset} : |\text{v128}|/8] = b^*]; \epsilon && \text{if } b^* = \text{bytes}_{\text{v128}}(c)
 \end{aligned}$$

v128.storeN_lane $x \text{ } ao \text{ } j$

1. Let z be the current state.
2. Assert: Due to **validation**, a value of **vector type v128** is on the top of the stack.
3. Pop the value $(\text{v128.const } c)$ from the stack.

4. Assert: Due to **validation**, a **number value** is on the top of the stack.
5. Pop the value (*at.const i*) from the stack.
6. If $i + ao.offset + N > |z.mems[x].bytes|$, then:
 - a. Trap.
7. Let M be $128/N$.
8. Let iN be the result for which $|iN| = N$.
9. Assert: Due to **validation**, $j < |\text{lanes}_{iN \times M}(c)|$.
10. Let b^* be $\text{bytes}_{iN}(\text{lanes}_{iN \times M}(c)[j])$.
11. Replace $z.mems[x].bytes[i + ao.offset : N/8]$ with b^* .

$$\begin{aligned}
 z; (at.const\ i) \ (v128.const\ c) \ (v128.storeN_lane\ x\ ao\ j) &\hookrightarrow z; \text{trap} && \text{if } i + ao.offset + N > |z.mems[x].bytes| \\
 z; (at.const\ i) \ (v128.const\ c) \ (v128.storeN_lane\ x\ ao\ j) &\hookrightarrow z[.mems[x].bytes[i + ao.offset : N/8] = b^*]; \epsilon && \text{if } N = |iN| \\
 &&& \wedge M = 128/N \\
 &&& \wedge b^* = \text{bytes}_{iN}(\text{lanes}_{iN \times M}(c)[j])
 \end{aligned}$$

memory.size x

1. Let z be the current state.
2. Let (*at.lim page*) be the destructuring of $z.mems[x].type$.
3. Let $n \cdot 64\text{ Ki}$ be the length of $z.mems[x].bytes$.
4. Push the value (*at.const n*) to the stack.

$$\begin{aligned}
 z; (\text{memory.size } x) &\hookrightarrow (at.const\ n) && \text{if } n \cdot 64\text{ Ki} = |z.mems[x].bytes| \\
 &&& \wedge z.mems[x].type = at.lim\ page
 \end{aligned}$$

memory.grow x

1. Let z be the current state.
2. Assert: Due to **validation**, a **number value** is on the top of the stack.
3. Pop the value (*at.const n*) from the stack.
4. Either:
 - a. Let mi be the **memory instance** $\text{growmem}(z.mems[x], n)$.
 - b. Push the value (*at.const $|z.mems[x].bytes|/(64\text{ Ki})$*) to the stack.
 - c. Replace $z.mems[x]$ with mi .
5. Or:
 - a. Push the value (*at.const $\text{signed}_{|at|}^{-1}(-1)$*) to the stack.

$$\begin{aligned}
 z; (at.const\ n) \ (\text{memory.grow } x) &\hookrightarrow z[.mems[x] = mi]; (at.const\ |z.mems[x].bytes|/64\text{ Ki}) && \text{if } mi = \text{growmem}(z.mems[x], n) \\
 &&& \\
 z; (at.const\ n) \ (\text{memory.grow } x) &\hookrightarrow z; (at.const\ \text{signed}_{|at|}^{-1}(-1))
 \end{aligned}$$

Note

The **memory.grow** instruction is non-deterministic. It may either succeed, returning the old memory size sz , or fail, returning -1 . Failure *must* occur if the referenced memory instance has a maximum size defined that would be exceeded. However, failure *can* occur in other cases as well. In practice, the choice depends on the **resources** available to the **embedder**.

memory.fill x

1. Let z be the current state.
 2. Assert: Due to *validation*, a *number value* is on the top of the stack.
 3. Pop the value ($at.const\ n$) from the stack.
 4. Assert: Due to *validation*, a value is on the top of the stack.
 5. Pop the value *val* from the stack.
 6. Assert: Due to *validation*, a value of *number type* at is on the top of the stack.
 7. Pop the value ($numtype_0.const\ i$) from the stack.
 8. If $i + n > |z.mems[x].bytes|$, then:
 - a. Trap.
 9. If $n = 0$, then:
 - a. Do nothing.
 10. Else:
 - a. Push the value ($at.const\ i$) to the stack.
 - b. Push the value *val* to the stack.
 - c. Execute the instruction ($i32.store8\ x$).
 - d. Push the value ($at.const\ i + 1$) to the stack.
 - e. Push the value *val* to the stack.
 - f. Push the value ($at.const\ n - 1$) to the stack.
 - g. Execute the instruction (*memory.fill* x).
- $$\begin{array}{ll}
 z; (at.const\ i)\ val\ (at.const\ n)\ (memory.fill\ x) & \hookrightarrow \text{trap} \quad \text{if } i + n > |z.mems[x].bytes| \\
 z; (at.const\ i)\ val\ (at.const\ n)\ (memory.fill\ x) & \hookrightarrow \epsilon \quad \text{otherwise, if } n = 0 \\
 z; (at.const\ i)\ val\ (at.const\ n)\ (memory.fill\ x) & \hookrightarrow \\
 \quad (at.const\ i)\ val\ (i32.store8\ x) & \text{otherwise} \\
 \quad (at.const\ i + 1)\ val\ (at.const\ n - 1)\ (memory.fill\ x) &
 \end{array}$$

memory.copy $x_1\ x_2$

1. Let z be the current state.
2. Assert: Due to *validation*, a *number value* is on the top of the stack.
3. Pop the value ($at.const\ n$) from the stack.
4. Assert: Due to *validation*, a *number value* is on the top of the stack.
5. Pop the value ($at_2.const\ i_2$) from the stack.
6. Assert: Due to *validation*, a *number value* is on the top of the stack.
7. Pop the value ($at_1.const\ i_1$) from the stack.
8. If $i_1 + n > |z.mems[x_1].bytes|$, then:
 - a. Trap.
9. If $i_2 + n > |z.mems[x_2].bytes|$, then:
 - a. Trap.
10. If $n = 0$, then:
 - a. Do nothing.
11. Else:

- a. If $i_1 \leq i_2$, then:
 - 1) Push the value $(at_1.\text{const } i_1)$ to the stack.
 - 2) Push the value $(at_2.\text{const } i_2)$ to the stack.
 - 3) Execute the instruction $(i32.\text{load8_u } x_2)$.
 - 4) Execute the instruction $(i32.\text{store8 } x_1)$.
 - 5) Push the value $(at_1.\text{const } i_1 + 1)$ to the stack.
 - 6) Push the value $(at_2.\text{const } i_2 + 1)$ to the stack.
- b. Else:
 - 1) Push the value $(at_1.\text{const } i_1 + n - 1)$ to the stack.
 - 2) Push the value $(at_2.\text{const } i_2 + n - 1)$ to the stack.
 - 3) Execute the instruction $(i32.\text{load8_u } x_2)$.
 - 4) Execute the instruction $(i32.\text{store8 } x_1)$.
 - 5) Push the value $(at_1.\text{const } i_1)$ to the stack.
 - 6) Push the value $(at_2.\text{const } i_2)$ to the stack.
- c. Push the value $(at.\text{const } n - 1)$ to the stack.
- d. Execute the instruction $(\text{memory.copy } x_1 x_2)$.

$$\begin{aligned}
 z; (at_1.\text{const } i_1) (at_2.\text{const } i_2) (at'.\text{const } n) (\text{memory.copy } x_1 x_2) &\hookrightarrow \text{trap} \\
 &\quad \text{if } i_1 + n > |z.\text{mems}[x_1].\text{bytes}| \vee i_2 + n > |z.\text{mems}[x_2].\text{bytes}| \\
 z; (at_1.\text{const } i_1) (at_2.\text{const } i_2) (at'.\text{const } n) (\text{memory.copy } x_1 x_2) &\hookrightarrow \epsilon && \text{otherwise, if } n = 0 \\
 z; (at_1.\text{const } i_1) (at_2.\text{const } i_2) (at'.\text{const } n) (\text{memory.copy } x_1 x_2) &\hookrightarrow \\
 (at_1.\text{const } i_1) (at_2.\text{const } i_2) (i32.\text{load8_u } x_2) (i32.\text{store8 } x_1) &&& \text{otherwise, if } i_1 \leq i_2 \\
 (at_1.\text{const } i_1 + 1) (at_2.\text{const } i_2 + 1) (at'.\text{const } n - 1) (\text{memory.copy } x_1 x_2) &&& \\
 z; (at_1.\text{const } i_1) (at_2.\text{const } i_2) (at'.\text{const } n) (\text{memory.copy } x_1 x_2) &\hookrightarrow \\
 (at_1.\text{const } i_1 + n - 1) (at_2.\text{const } i_2 + n - 1) (i32.\text{load8_u } x_2) (i32.\text{store8 } x_1) &&& \text{otherwise} \\
 (at_1.\text{const } i_1) (at_2.\text{const } i_2) (at'.\text{const } n - 1) (\text{memory.copy } x_1 x_2) &&&
 \end{aligned}$$

$\text{memory.init } x y$

1. Let z be the current state.
2. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.
3. Pop the value $(i32.\text{const } n)$ from the stack.
4. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.
5. Pop the value $(i32.\text{const } j)$ from the stack.
6. Assert: Due to **validation**, a **number value** is on the top of the stack.
7. Pop the value $(at.\text{const } i)$ from the stack.
8. If $i + n > |z.\text{mems}[x].\text{bytes}|$, then:
 - a. Trap.
9. If $j + n > |z.\text{datas}[y].\text{bytes}|$, then:
 - a. Trap.
10. If $n = 0$, then:
 - a. Do nothing.
11. Else:
 - a. Assert: Due to **validation**, $j < |z.\text{datas}[y].\text{bytes}|$.

- b. Push the value $(at.const\ i)$ to the stack.
- c. Push the value $(i32.const\ z.datas[y].bytes[j])$ to the stack.
- d. Execute the instruction $(i32.store8\ x)$.
- e. Push the value $(at.const\ i + 1)$ to the stack.
- f. Push the value $(i32.const\ j + 1)$ to the stack.
- g. Push the value $(i32.const\ n - 1)$ to the stack.
- h. Execute the instruction $(memory.init\ x\ y)$.

$$\begin{aligned}
 z; (at.const\ i) (i32.const\ j) (i32.const\ n) (memory.init\ x\ y) &\hookrightarrow \text{trap} \\
 &\quad \text{if } i + n > |z.mems[x].bytes| \vee j + n > |z.datas[y].bytes| \\
 z; (at.const\ i) (i32.const\ j) (i32.const\ n) (memory.init\ x\ y) &\hookrightarrow \epsilon && \text{otherwise, if } n = 0 \\
 z; (at.const\ i) (i32.const\ j) (i32.const\ n) (memory.init\ x\ y) &\hookrightarrow \\
 &\quad (at.const\ i) (i32.const\ z.datas[y].bytes[j]) (i32.store8\ x) && \text{otherwise} \\
 &\quad (at.const\ i + 1) (i32.const\ j + 1) (i32.const\ n - 1) (memory.init\ x\ y)
 \end{aligned}$$

$data.drop\ x$

1. Let z be the current state.
2. Replace $z.datas[x].bytes$ with ϵ .

$$z; (data.drop\ x) \hookrightarrow z[.datas[x].bytes = \epsilon]; \epsilon$$

4.6.9 Reference Instructions

$ref.null\ x$

1. Let F be the [current frame](#).
2. Assert: due to [validation](#), the [defined type](#) $F.module.types[x]$ exists.
3. Let $deftype$ be the [defined type](#) $F.module.types[x]$.
4. Push the value $ref.null\ deftype$ to the stack.

$$z; (ref.null\ x) \hookrightarrow (ref.null\ z.types[x])$$

Note

No formal reduction rule is required for the case $ref.null\ absheapttype$, since the instruction form is already a [value](#).

$ref.func\ x$

1. Let z be the current state.
2. Assert: Due to [validation](#), $x < |z.module.funcs|$.
3. Push the value $(ref.func\ z.module.funcs[x])$ to the stack.

$$z; (ref.func\ x) \hookrightarrow (ref.func\ z.module.funcs[x])$$

ref.is_null

1. Assert: Due to **validation**, a **reference value** is on the top of the stack.
2. Pop the value *ref* from the stack.
3. If *ref* is some *ref.null heaptypes*, then:
 - a. Push the value (*i32.const* 1) to the stack.
4. Else:
 - a. Push the value (*i32.const* 0) to the stack.

$$\begin{aligned} \text{ref } \text{ref.is_null} &\hookrightarrow (\text{i32.const } 1) && \text{if } \text{ref} = (\text{ref.null } ht) \\ \text{ref } \text{ref.is_null} &\hookrightarrow (\text{i32.const } 0) && \text{otherwise} \end{aligned}$$
ref.as_non_null

1. Assert: Due to **validation**, a **reference value** is on the top of the stack.
2. Pop the value *ref* from the stack.
3. If *ref* is some *ref.null heaptypes*, then:
 - a. Trap.
4. Push the value *ref* to the stack.

$$\begin{aligned} \text{ref } \text{ref.as_non_null} &\hookrightarrow \text{trap} && \text{if } \text{ref} = (\text{ref.null } ht) \\ \text{ref } \text{ref.as_non_null} &\hookrightarrow \text{ref} && \text{otherwise} \end{aligned}$$
ref.eq

1. Assert: Due to **validation**, a **reference value** is on the top of the stack.
2. Pop the value *ref*₂ from the stack.
3. Assert: Due to **validation**, a **reference value** is on the top of the stack.
4. Pop the value *ref*₁ from the stack.
5. If *ref*₁ is some *ref.null heaptypes* and *ref*₂ is some *ref.null heaptypes*, then:
 - a. Push the value (*i32.const* 1) to the stack.
6. Else if *ref*₁ = *ref*₂, then:
 - a. Push the value (*i32.const* 1) to the stack.
7. Else:
 - a. Push the value (*i32.const* 0) to the stack.

$$\begin{aligned} \text{ref}_1 \text{ ref}_2 \text{ ref.eq} &\hookrightarrow (\text{i32.const } 1) && \text{if } \text{ref}_1 = (\text{ref.null } ht_1) \wedge \text{ref}_2 = (\text{ref.null } ht_2) \\ \text{ref}_1 \text{ ref}_2 \text{ ref.eq} &\hookrightarrow (\text{i32.const } 1) && \text{otherwise, if } \text{ref}_1 = \text{ref}_2 \\ \text{ref}_1 \text{ ref}_2 \text{ ref.eq} &\hookrightarrow (\text{i32.const } 0) && \text{otherwise} \end{aligned}$$
ref.test rt

1. Let *f* be the topmost frame.
2. Assert: Due to **validation**, a **reference value** is on the top of the stack.
3. Pop the value *ref* from the stack.
4. Let *rt'* be the type of *ref*.
5. If *rt'* matches *close_f.module*(*rt*), then:
 - a. Push the value (*i32.const* 1) to the stack.
6. Else:

- a. Push the value $(i32.\text{const } 0)$ to the stack.

$$\begin{aligned} s; f; \text{ref} (\text{ref.test } rt) &\hookrightarrow (i32.\text{const } 1) && \text{if } s \vdash \text{ref} : rt' \\ &&& \wedge \{\} \vdash rt' \leq \text{clos}_{f.\text{module}}(rt) \\ s; f; \text{ref} (\text{ref.test } rt) &\hookrightarrow (i32.\text{const } 0) && \text{otherwise} \end{aligned}$$

$\text{ref.cast } rt$

1. Let f be the topmost frame.
2. Assert: Due to **validation**, a **reference value** is on the top of the stack.
3. Pop the value ref from the stack.
4. Let rt' be the type of ref .
5. If rt' does not match $\text{clos}_{f.\text{module}}(rt)$, then:
 - a. Trap.
6. Push the value ref to the stack.

$$\begin{aligned} s; f; \text{ref} (\text{ref.cast } rt) &\hookrightarrow \text{ref} && \text{if } s \vdash \text{ref} : rt' \\ &&& \wedge \{\} \vdash rt' \leq \text{clos}_{f.\text{module}}(rt) \\ s; f; \text{ref} (\text{ref.cast } rt) &\hookrightarrow \text{trap} && \text{otherwise} \end{aligned}$$

ref.i31

1. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.
2. Pop the value $(i32.\text{const } i)$ from the stack.
3. Push the value $(\text{ref.i31 wrap}_{32,31}(i))$ to the stack.

$$(i32.\text{const } i) \text{ ref.i31} \hookrightarrow (\text{ref.i31 wrap}_{32,31}(i))$$

$i31.\text{get_sx}$

1. Assert: Due to **validation**, a value is on the top of the stack.
2. Pop the value val from the stack.
3. If val is some $\text{ref.null heapttype}$, then:
 - a. Trap.
4. Assert: Due to **validation**, val is some $\text{ref.i31 } u_{31}$.
5. Let $(\text{ref.i31 } i)$ be the destructuring of val .
6. Push the value $(i32.\text{const extend}_{31,32}^{\text{sx}}(i))$ to the stack.

$$\begin{aligned} (\text{ref.null } ht) (i31.\text{get_sx}) &\hookrightarrow \text{trap} \\ (\text{ref.i31 } i) (i31.\text{get_sx}) &\hookrightarrow (i32.\text{const extend}_{31,32}^{\text{sx}}(i)) \end{aligned}$$

$\text{struct.new } x$

1. Let z be the current state.
2. Assert: Due to **validation**, the expansion of $z.\text{types}[x]$ is some $\text{struct list}(\text{fieldtype})$.
3. Let $(\text{struct } list_0)$ be the destructuring of the expansion of $z.\text{types}[x]$.
4. Let $(\text{mut}^? \text{zt})^n$ be $list_0$.
5. Let a be the length of $z.\text{structs}$.
6. Assert: Due to **validation**, there are at least n values on the top of the stack.
7. Pop the values val^n from the stack.

8. Let si be the **structure** instance $\{\text{type } z.\text{types}[x], \text{fields } \text{pack}_{zt}(val)^n\}$.

9. Push the value $(\text{ref.struct } a)$ to the stack.

10. Append si to $z.\text{structs}$.

$$z; val^n (\text{struct.new } x) \hookrightarrow z[.structs = \oplus si]; (\text{ref.struct } a) \quad \begin{array}{l} \text{if } z.\text{types}[x] \approx \text{struct } (\text{mut}^? zt)^n \\ \wedge a = |z.\text{structs}| \\ \wedge si = \{\text{type } z.\text{types}[x], \text{fields } (\text{pack}_{zt}(val))^n\} \end{array}$$

struct.new_default x

1. Let z be the current state.

2. Assert: Due to **validation**, the **expansion** of $z.\text{types}[x]$ is some **struct** $list(\text{fieldtype})$.

3. Let $(\text{struct } list_0)$ be the destructuring of the **expansion** of $z.\text{types}[x]$.

4. Let $(\text{mut}^? zt)^*$ be $list_0$.

5. Assert: Due to **validation**, for all zt in zt^* , $\text{default}_{\text{unpack}(zt)}$ is defined.

6. Let val^* be $\text{default}_{\text{unpack}(zt)}^*$.

7. Assert: Due to **validation**, $|val^*| = |zt^*|$.

8. Push the values val^* to the stack.

9. Execute the instruction $(\text{struct.new } x)$.

$$z; (\text{struct.new_default } x) \hookrightarrow val^* (\text{struct.new } x) \quad \begin{array}{l} \text{if } z.\text{types}[x] \approx \text{struct } (\text{mut}^? zt)^* \\ \wedge (\text{default}_{\text{unpack}(zt)} = val)^* \end{array}$$

struct.get_sx? $x \ i$

1. Let z be the current state.

2. Assert: Due to **validation**, a value is on the top of the stack.

3. Pop the value val from the stack.

4. If val is some **ref.null** *heapttype*, then:

a. Trap.

5. Assert: Due to **validation**, val is some **ref.struct** *structaddr*.

6. Let $(\text{ref.struct } a)$ be the destructuring of val .

7. Assert: Due to **validation**, $i < |z.\text{structs}[a].\text{fields}|$.

8. Assert: Due to **validation**, $a < |z.\text{structs}|$.

9. Assert: Due to **validation**, the **expansion** of $z.\text{types}[x]$ is some **struct** $list(\text{fieldtype})$.

10. Let $(\text{struct } list_0)$ be the destructuring of the **expansion** of $z.\text{types}[x]$.

11. Let $(\text{mut}^? zt)^*$ be $list_0$.

12. Assert: Due to **validation**, $i < |zt^*|$.

13. Push the value $\text{unpack}_{zt^*[i]}^{sx?}(z.\text{structs}[a].\text{fields}[i])$ to the stack.

$$z; (\text{ref.null } ht) (\text{struct.get_sx? } x \ i) \hookrightarrow \text{trap}$$

$$z; (\text{ref.struct } a) (\text{struct.get_sx? } x \ i) \hookrightarrow \text{unpack}_{zt^*[i]}^{sx?}(z.\text{structs}[a].\text{fields}[i]) \quad \text{if } z.\text{types}[x] \approx \text{struct } (\text{mut}^? zt)^*$$

struct.set $x\ i$

1. Let z be the current state.
2. Assert: Due to **validation**, a value is on the top of the stack.
3. Pop the value val from the stack.
4. Assert: Due to **validation**, a value is on the top of the stack.
5. Pop the value val' from the stack.
6. If val' is some **ref.null heaptypes**, then:
 - a. Trap.
7. Assert: Due to **validation**, val' is some **ref.struct structaddr**.
8. Let $(\text{ref.struct } a)$ be the destructuring of val' .
9. Assert: Due to **validation**, the **expansion** of $z.\text{types}[x]$ is some **struct list(fieldtype)**.
10. Let (struct list_0) be the destructuring of the **expansion** of $z.\text{types}[x]$.
11. Let $(\text{mut}^? \text{zt})^*$ be list_0 .
12. Assert: Due to **validation**, $i < |\text{zt}^*|$.
13. Replace $z.\text{structs}[a].\text{fields}[i]$ with $\text{pack}_{\text{zt}^*[i]}(val)$.

$$z; (\text{ref.null ht})\ val\ (\text{struct.set } x\ i) \quad \hookrightarrow \quad z; \text{trap}$$

$$z; (\text{ref.struct } a)\ val\ (\text{struct.set } x\ i) \quad \hookrightarrow \quad z[\text{structs}[a].\text{fields}[i] = \text{pack}_{\text{zt}^*[i]}(val)]; \epsilon \quad \text{if } z.\text{types}[x] \approx \text{struct } (\text{mut}^? \text{zt})^*$$
array.new x

1. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.
2. Pop the value $(\text{i32.const } n)$ from the stack.
3. Assert: Due to **validation**, a value is on the top of the stack.
4. Pop the value val from the stack.
5. Push the values val^n to the stack.
6. Execute the instruction **(array.new_fixed $x\ n$)**.

$$val\ (\text{i32.const } n)\ (\text{array.new } x) \quad \hookrightarrow \quad val^n\ (\text{array.new_fixed } x\ n)$$
array.new_default x

1. Let z be the current state.
2. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.
3. Pop the value $(\text{i32.const } n)$ from the stack.
4. Assert: Due to **validation**, the **expansion** of $z.\text{types}[x]$ is some **array fieldtype**.
5. Let $(\text{array fieldtype}_0)$ be the destructuring of the **expansion** of $z.\text{types}[x]$.
6. Let $(\text{mut}^? \text{zt})$ be the destructuring of fieldtype_0 .
7. Assert: Due to **validation**, $\text{default}_{\text{unpack}(\text{zt})}$ is defined.
8. Let val be $\text{default}_{\text{unpack}(\text{zt})}$.
9. Push the values val^n to the stack.
10. Execute the instruction **(array.new_fixed $x\ n$)**.

$$z; (\text{i32.const } n)\ (\text{array.new_default } x) \quad \hookrightarrow \quad val^n\ (\text{array.new_fixed } x\ n) \quad \text{if } z.\text{types}[x] \approx \text{array } (\text{mut}^? \text{zt})$$

$$\quad \wedge \text{default}_{\text{unpack}(\text{zt})} = val$$

`array.new_fixed` $x\ n$

1. Let z be the current state.
2. Assert: Due to **validation**, the expansion of $z.types[x]$ is some *array fieldtype*.
3. Let $(array\ fieldtype_0)$ be the destructuring of the expansion of $z.types[x]$.
4. Let $(mut^? zt)$ be the destructuring of $fieldtype_0$.
5. Let a be the length of $z.arrays$.
6. Assert: Due to **validation**, there are at least n values on the top of the stack.
7. Pop the values val^n from the stack.
8. Let ai be the array instance $\{type\ z.types[x],\ fields\ pack_{zt}(val)^n\}$.
9. Push the value $(ref.array\ a)$ to the stack.
10. Append ai to $z.arrays$.

$$z; val^n (array.new_fixed\ x\ n) \hookrightarrow z[.arrays = \oplus ai]; (ref.array\ a) \\ \text{if } z.types[x] \approx array\ (mut^? zt) \\ \wedge a = |z.arrays| \wedge ai = \{type\ z.types[x],\ fields\ (pack_{zt}(val))^n\}$$

`array.new_data` $x\ y$

1. Let z be the current state.
2. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.
3. Pop the value $(i32.const\ n)$ from the stack.
4. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.
5. Pop the value $(i32.const\ i)$ from the stack.
6. Assert: Due to **validation**, the expansion of $z.types[x]$ is some *array fieldtype*.
7. Let $(array\ fieldtype_0)$ be the destructuring of the expansion of $z.types[x]$.
8. Let $(mut^? zt)$ be the destructuring of $fieldtype_0$.
9. If $i + n \cdot |zt|/8 > |z.datas[y].bytes|$, then:
 - a. Trap.
10. Let $byte^{**}$ be the result for which each $byte^*$ has length $|zt|/8$, and the concatenation of $byte^{**}$ is $z.datas[y].bytes[i : n \cdot |zt|/8]$.
11. Let c^n be the result for which $(bytes_{zt}(c^n) = byte^*)^*$.
12. Push the values $unpack(zt).const\ unpack_{zt}(c)^n$ to the stack.
13. Execute the instruction `(array.new_fixed` $x\ n)$.

$$z; (i32.const\ i)\ (i32.const\ n)\ (array.new_data\ x\ y) \hookrightarrow \text{trap} \\ \text{if } z.types[x] \approx array\ (mut^? zt) \\ \wedge i + n \cdot |zt|/8 > |z.datas[y].bytes| \\ z; (i32.const\ i)\ (i32.const\ n)\ (array.new_data\ x\ y) \hookrightarrow (unpack(zt).const\ unpack_{zt}(c))^n\ (array.new_fixed\ x\ n) \\ \text{if } z.types[x] \approx array\ (mut^? zt) \\ \wedge \oplus bytes_{zt}(c)^n = z.datas[y].bytes[i : n \cdot |zt|/8]$$

`array.new_elem` $x\ y$

1. Let z be the current state.
2. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.
3. Pop the value $(i32.const\ n)$ from the stack.

4. Assert: Due to **validation**, a value of **number type** `i32` is on the top of the stack.
5. Pop the value `(i32.const i)` from the stack.
6. If $i + n > |z.\text{elems}[y].\text{elem}|$, then:
 - a. Trap.
7. Let ref^n be $z.\text{elems}[y].\text{elem}[i : n]$.
8. Push the values ref^n to the stack.
9. Execute the instruction `(array.new_fixed x n)`.

$$\begin{aligned} z; (i32.\text{const } i) (i32.\text{const } n) (\text{array.new_elem } x y) &\hookrightarrow \text{trap} && \text{if } i + n > |z.\text{elems}[y].\text{elem}| \\ z; (i32.\text{const } i) (i32.\text{const } n) (\text{array.new_elem } x y) &\hookrightarrow \text{ref}^n (\text{array.new_fixed } x n) && \text{if } \text{ref}^n = z.\text{elems}[y].\text{elem}[i : n] \end{aligned}$$

`array.getsx? x`

1. Let z be the current state.
2. Assert: Due to **validation**, a value of **number type** `i32` is on the top of the stack.
3. Pop the value `(i32.const i)` from the stack.
4. Assert: Due to **validation**, a value is on the top of the stack.
5. Pop the value val from the stack.
6. If val is some `ref.null heaptype`, then:
 - a. Trap.
7. Assert: Due to **validation**, val is some `ref.array arrayaddr`.
8. Let `(ref.array a)` be the destructuring of val .
9. If $a < |z.\text{arrays}|$ and $i \geq |z.\text{arrays}[a].\text{fields}|$, then:
 - a. Trap.
10. If $i < |z.\text{arrays}[a].\text{fields}|$ and $a < |z.\text{arrays}|$, then:
 - a. Assert: Due to **validation**, the expansion of $z.\text{types}[x]$ is some array *fieldtype*.
 - b. Let `(array fieldtype0)` be the destructuring of the expansion of $z.\text{types}[x]$.
 - c. Let `(mut? zt)` be the destructuring of *fieldtype₀*.
 - d. Push the value $\text{unpack}_{zt}^{sx?}(z.\text{arrays}[a].\text{fields}[i])$ to the stack.

$$\begin{aligned} z; (\text{ref.null } ht) (i32.\text{const } i) (\text{array.get}_{sx?} x) &\hookrightarrow \text{trap} \\ z; (\text{ref.array } a) (i32.\text{const } i) (\text{array.get}_{sx?} x) &\hookrightarrow \text{trap} && \text{if } i \geq |z.\text{arrays}[a].\text{fields}| \\ z; (\text{ref.array } a) (i32.\text{const } i) (\text{array.get}_{sx?} x) &\hookrightarrow \text{unpack}_{zt}^{sx?}(z.\text{arrays}[a].\text{fields}[i]) && \text{if } z.\text{types}[x] \approx \text{array}(\text{mut}^? zt) \end{aligned}$$

`array.set x`

1. Let z be the current state.
2. Assert: Due to **validation**, a value is on the top of the stack.
3. Pop the value val from the stack.
4. Assert: Due to **validation**, a value of **number type** `i32` is on the top of the stack.
5. Pop the value `(i32.const i)` from the stack.
6. Assert: Due to **validation**, a value is on the top of the stack.
7. Pop the value val' from the stack.

8. If val' is some `ref.null heaptypes`, then:
 - a. Trap.
 9. Assert: Due to `validation`, val' is some `ref.array arrayaddr`.
 10. Let $(ref.array\ a)$ be the destructuring of val' .
 11. If $a < |z.arrays|$ and $i \geq |z.arrays[a].fields|$, then:
 - a. Trap.

2. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.
3. Pop the value (`i32.const n`) from the stack.
4. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.
5. Pop the value (`i32.const j`) from the stack.
6. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.
7. Pop the value (`i32.const i`) from the stack.
8. Assert: Due to **validation**, a value is on the top of the stack.
9. Pop the value *val* from the stack.
10. If *val* is some `ref.null heapttype`, then:
 - a. Trap.
11. Assert: Due to **validation**, *val* is some `ref.array arrayaddr`.

12. Let $(\text{ref.array } a)$ be the destructuring of val .
13. If $a < |z.arrays|$ and $i + n > |z.arrays[a].fields|$, then:
 - a. Trap.
14. If $j + n > |z.elems[y].elem|$, then:
 - a. Trap.
15. If $n = 0$, then:
 - a. Do nothing.

16. Else if $j < |z.elems[y].elem|$, then:

- a. Let ref be the reference value $z.elems[y].elem[j]$.
- b. Push the value $(\text{ref.array } a)$ to the stack.
- c. Push the value $(i32.const \ i)$ to the stack.
- d. Push the value ref to the stack.
- e. Execute the instruction $(\text{array.set } x)$.
- f. Push the value $(\text{ref.array } a)$ to the stack.
- g. Push the value $(i32.const \ i + 1)$ to the stack.
- h. Push the value $(i32.const \ j + 1)$ to the stack.
- i. Push the value $(i32.const \ n - 1)$ to the stack.
- j. Execute the instruction $(\text{array.init_elem } x \ y)$.

$$\begin{aligned}
 &z; (\text{ref.null } ht) \ (i32.const \ i) \ (i32.const \ j) \ (i32.const \ n) \ (\text{array.init_elem } x \ y) \hookrightarrow \text{trap} \\
 &z; (\text{ref.array } a) \ (i32.const \ i) \ (i32.const \ j) \ (i32.const \ n) \ (\text{array.init_elem } x \ y) \hookrightarrow \text{trap} \\
 &\quad \text{if } i + n > |z.arrays[a].fields| \\
 &z; (\text{ref.array } a) \ (i32.const \ i) \ (i32.const \ j) \ (i32.const \ n) \ (\text{array.init_elem } x \ y) \hookrightarrow \text{trap} \\
 &\quad \text{if } j + n > |z.elems[y].elem| \\
 &z; (\text{ref.array } a) \ (i32.const \ i) \ (i32.const \ j) \ (i32.const \ n) \ (\text{array.init_elem } x \ y) \hookrightarrow \epsilon \\
 &\quad \text{otherwise, if } n = 0 \\
 &z; (\text{ref.array } a) \ (i32.const \ i) \ (i32.const \ j) \ (i32.const \ n) \ (\text{array.init_elem } x \ y) \hookrightarrow \\
 &\quad (\text{ref.array } a) \ (i32.const \ i) \ ref \ (\text{array.set } x) \\
 &\quad (\text{ref.array } a) \ (i32.const \ i + 1) \ (i32.const \ j + 1) \ (i32.const \ n - 1) \ (\text{array.init_elem } x \ y) \\
 &\quad \text{otherwise, if } ref = z.elems[y].elem[j]
 \end{aligned}$$

`any.convert_extern`

1. Assert: Due to [validation](#), a value is on the top of the stack.
2. Pop the value val from the stack.
3. If val is some $\text{ref.null } heapttype$, then:
 - a. Push the value $(\text{ref.null } any)$ to the stack.
4. If val is some $\text{ref.extern } addrref$, then:
 - a. Let $(\text{ref.extern } addrref)$ be the destructuring of val .
 - b. Push the value $addrref$ to the stack.

$$\begin{aligned}
 &(\text{ref.null } ht) \ \text{any.convert_extern} \hookrightarrow (\text{ref.null } any) \\
 &(\text{ref.extern } addrref) \ \text{any.convert_extern} \hookrightarrow addrref
 \end{aligned}$$

extern.convert_any

1. Assert: Due to [validation](#), a value is on the top of the stack.
2. Pop the value *val* from the stack.
3. If *val* is some *ref.null heaptypes*, then:
 - a. Push the value (*ref.null extern*) to the stack.
4. If *val* is address value, then:
 - a. Push the value (*ref.extern val*) to the stack.

$$\begin{aligned} (\text{ref.null ht}) \text{extern.convert_any} &\hookrightarrow (\text{ref.null extern}) \\ \text{addrref extern.convert_any} &\hookrightarrow (\text{ref.extern addrref}) \end{aligned}$$

4.6.10 Numeric Instructions

Numeric instructions are defined in terms of the generic [numeric operators](#). The mapping of numeric instructions to their underlying operators is expressed by the following definition:

$$\begin{aligned} op_{iN}(i_1, \dots, i_k) &= iop_N(i_1, \dots, i_k) \\ op_{fN}(z_1, \dots, z_k) &= fop_N(z_1, \dots, z_k) \end{aligned}$$

And for [conversion operators](#):

$$cvtop_{t_1, t_2}^{sx?}(c) = cvtop_{|t_1|, |t_2|}^{sx?}(c)$$

Where the underlying operators are partial, the corresponding instruction will [trap](#) when the result is not defined. Where the underlying operators are non-deterministic, because they may return one of multiple possible NaN values, so are the corresponding instructions.

Note

For example, the result of instruction *i32.add* applied to operands *i*₁, *i*₂ invokes *add*_{i32}(*i*₁, *i*₂), which maps to the generic *iadd*₃₂(*i*₁, *i*₂) via the above definition. Similarly, *i64.trunc_f32_s* applied to *z* invokes *trunc*_{f32, i64}^s(*z*), which maps to the generic *trunc*_{32, 64}^s(*z*).

nt.const c

1. Push the value (*nt.const c*) to the stack.

Note

No formal reduction rule is required for this instruction, since *const* instructions already are [values](#).

nt.unop

1. Assert: Due to [validation](#), a value of [number type](#) *nt* is on the top of the stack.
2. Pop the value (*numtype*₀.*const c*₁) from the stack.
3. If *unop*_{nt}(*c*₁) is empty, then:
 - a. Trap.
4. Let *c* be an element of *unop*_{nt}(*c*₁).
5. Push the value (*nt.const c*) to the stack.

$$\begin{aligned} (\text{nt.const } c_1) (\text{nt.unop}) &\hookrightarrow (\text{nt.const } c) && \text{if } c \in \text{unop}_{nt}(c_1) \\ (\text{nt.const } c_1) (\text{nt.unop}) &\hookrightarrow \text{trap} && \text{if } \text{unop}_{nt}(c_1) = \epsilon \end{aligned}$$

nt.binop

1. Assert: Due to [validation](#), a value of [number type](#) *nt* is on the top of the stack.
2. Pop the value (*numtype*₀.const *c*₂) from the stack.
3. Assert: Due to [validation](#), a [number value](#) is on the top of the stack.
4. Pop the value (*numtype*₀.const *c*₁) from the stack.
5. If *binop*_{*nt*}(*c*₁, *c*₂) is empty, then:
 - a. Trap.
6. Let *c* be an element of *binop*_{*nt*}(*c*₁, *c*₂).
7. Push the value (*nt*.const *c*) to the stack.

$$\begin{aligned}
 (nt.const\ c_1)\ (nt.const\ c_2)\ (nt.binop) &\hookrightarrow (nt.const\ c) && \text{if } c \in binop_{nt}(c_1, c_2) \\
 (nt.const\ c_1)\ (nt.const\ c_2)\ (nt.binop) &\hookrightarrow \text{trap} && \text{if } binop_{nt}(c_1, c_2) = \epsilon
 \end{aligned}$$

nt.testop

1. Assert: Due to [validation](#), a value of [number type](#) *nt* is on the top of the stack.
2. Pop the value (*numtype*₀.const *c*₁) from the stack.
3. Let *c* be *testop*_{*nt*}(*c*₁).
4. Push the value (*i32*.const *c*) to the stack.

$$(nt.const\ c_1)\ (nt.testop) \hookrightarrow (i32.const\ c) \quad \text{if } c = testop_{nt}(c_1)$$

nt.relop

1. Assert: Due to [validation](#), a value of [number type](#) *nt* is on the top of the stack.
2. Pop the value (*numtype*₀.const *c*₂) from the stack.
3. Assert: Due to [validation](#), a [number value](#) is on the top of the stack.
4. Pop the value (*numtype*₀.const *c*₁) from the stack.
5. Let *c* be *relop*_{*nt*}(*c*₁, *c*₂).
6. Push the value (*i32*.const *c*) to the stack.

$$(nt.const\ c_1)\ (nt.const\ c_2)\ (nt.relop) \hookrightarrow (i32.const\ c) \quad \text{if } c = relop_{nt}(c_1, c_2)$$

nt₂.cvtop_nt₁

1. Assert: Due to [validation](#), a value of [number type](#) *nt*₁ is on the top of the stack.
2. Pop the value (*numtype*₀.const *c*₁) from the stack.
3. If *cvtop*_{*nt*₁,*nt*₂}(*c*₁) is empty, then:
 - a. Trap.
4. Let *c* be an element of *cvtop*_{*nt*₁,*nt*₂}(*c*₁).
5. Push the value (*nt*₂.const *c*) to the stack.

$$\begin{aligned}
 (nt_1.const\ c_1)\ (nt_2.cvtop_nt_1) &\hookrightarrow (nt_2.const\ c) && \text{if } c \in cvtop_{nt_1, nt_2}(c_1) \\
 (nt_1.const\ c_1)\ (nt_2.cvtop_nt_1) &\hookrightarrow \text{trap} && \text{if } cvtop_{nt_1, nt_2}(c_1) = \epsilon
 \end{aligned}$$

4.6.11 Vector Instructions

Vector instructions that operate bitwise are handled as integer operations of respective bit width.

$$op_{vN}(i_1, \dots, i_k) = iop_N(i_1, \dots, i_k)$$

Most other vector instructions are defined in terms of [numeric operators](#) that are applied lane-wise according to the given [shape](#).

$$op_{txN}(n_1, \dots, n_k) = \text{lanes}_{txN}^{-1}(op_t(i_1, \dots, i_k)^*) \quad (\text{if } i_1^* = \text{lanes}_{txN}(n_1) \wedge \dots \wedge i_k^* = \text{lanes}_{txN}(n_k))$$

Note

For example, the result of instruction `i32x4.add` applied to operands v_1, v_2 invokes `addi32x4(v_1, v_2)`, which maps to `lanesi32x4-1(addi32(i_1, i_2)*)`, where i_1^* and i_2^* are sequences resulting from invoking `lanesi32x4(v_1)` and `lanesi32x4(v_2)` respectively.

For non-deterministic operators this definition is generalized to sets:

$$op_{txN}(n_1, \dots, n_k) = \{\text{lanes}_{txN}^{-1}(i^*) \mid i^* \in \times(op_t(i_1, \dots, i_k)^*) \wedge i_1^* = \text{lanes}_{txN}(n_1) \wedge \dots \wedge i_k^* = \text{lanes}_{txN}(n_k)\}$$

where $\times\{x^*\}^N$ transforms a sequence of N sets of values into a set of sequences of N values by computing the set product:

$$\times(S_1 \dots S_N) = \{x_1 \dots x_N \mid x_1 \in S_1 \wedge \dots \wedge x_N \in S_N\}$$

The remaining vector operators use [individual definitions](#).

`v128.const c`

1. Push the value (`v128.const c`) to the stack.

Note

No formal reduction rule is required for this instruction, since `const` instructions are already [values](#).

`v128.vvunop`

1. Assert: Due to [validation](#), a value of [vector type v128](#) is on the top of the stack.
2. Pop the value (`v128.const c1`) from the stack.
3. Assert: Due to [validation](#), $|\text{vvunop}_{v128}(c_1)| > 0$.
4. Let c be an element of `vvunopv128(c_1)`.
5. Push the value (`v128.const c`) to the stack.

$$(\text{v128.const } c_1) (\text{v128.vvunop}) \hookrightarrow (\text{v128.const } c) \quad \text{if } c \in \text{vvunop}_{v128}(c_1)$$

`v128.vvbinop`

1. Assert: Due to [validation](#), a value of [vector type v128](#) is on the top of the stack.
2. Pop the value (`v128.const c2`) from the stack.
3. Assert: Due to [validation](#), a value of [vector type v128](#) is on the top of the stack.
4. Pop the value (`v128.const c1`) from the stack.
5. Assert: Due to [validation](#), $|\text{vvbinop}_{v128}(c_1, c_2)| > 0$.

6. Let c be an element of $vbinop_{v128}(c_1, c_2)$.

7. Push the value $(v128.const\ c)$ to the stack.

$$(v128.const\ c_1)\ (v128.const\ c_2)\ (v128.vbinop) \hookrightarrow (v128.const\ c) \quad \text{if } c \in vbinop_{v128}(c_1, c_2)$$

v128.vternop

1. Assert: Due to **validation**, a value of **vector type v128** is on the top of the stack.

2. Pop the value $(v128.const\ c_3)$ from the stack.

3. Assert: Due to **validation**, a value of **vector type v128** is on the top of the stack.

4. Pop the value $(v128.const\ c_2)$ from the stack.

5. Assert: Due to **validation**, a value of **vector type v128** is on the top of the stack.

6. Pop the value $(v128.const\ c_1)$ from the stack.

7. Assert: Due to **validation**, $|vternop_{v128}(c_1, c_2, c_3)| > 0$.

8. Let c be an element of $vternop_{v128}(c_1, c_2, c_3)$.

9. Push the value $(v128.const\ c)$ to the stack.

$$(v128.const\ c_1)\ (v128.const\ c_2)\ (v128.const\ c_3)\ (v128.vternop) \hookrightarrow (v128.const\ c) \\ \text{if } c \in vternop_{v128}(c_1, c_2, c_3)$$

v128.any_true

1. Assert: Due to **validation**, a value of **vector type v128** is on the top of the stack.

2. Pop the value $(v128.const\ c_1)$ from the stack.

3. Let c be $ine_{|v128|}(c_1, 0)$.

4. Push the value $(i32.const\ c)$ to the stack.

$$(v128.const\ c_1)\ (v128.any_true) \hookrightarrow (i32.const\ c) \quad \text{if } c = ine_{|v128|}(c_1, 0)$$

sh.vunop

1. Assert: Due to **validation**, a value of **vector type v128** is on the top of the stack.

2. Pop the value $(v128.const\ c_1)$ from the stack.

3. If $vunop_{sh}(c_1)$ is empty, then:

a. Trap.

4. Let c be an element of $vunop_{sh}(c_1)$.

5. Push the value $(v128.const\ c)$ to the stack.

$$(v128.const\ c_1)\ (sh.vunop) \hookrightarrow (v128.const\ c) \quad \text{if } c \in vunop_{sh}(c_1) \\ (v128.const\ c_1)\ (sh.vunop) \hookrightarrow \text{trap} \quad \text{if } vunop_{sh}(c_1) = \epsilon$$

sh.vbinop

1. Assert: Due to **validation**, a value of **vector type v128** is on the top of the stack.

2. Pop the value $(v128.const\ c_2)$ from the stack.

3. Assert: Due to **validation**, a value of **vector type v128** is on the top of the stack.

4. Pop the value $(v128.const\ c_1)$ from the stack.

5. If $vbinop_{sh}(c_1, c_2)$ is empty, then:

a. Trap.

6. Let c be an element of $vbinop_{sh}(c_1, c_2)$.

7. Push the value $(v128.const\ c)$ to the stack.

$$\begin{aligned} (v128.const\ c_1)\ (v128.const\ c_2)\ (sh.vbinop) &\hookrightarrow (v128.const\ c) && \text{if } c \in vbinop_{sh}(c_1, c_2) \\ (v128.const\ c_1)\ (v128.const\ c_2)\ (sh.vbinop) &\hookrightarrow \text{trap} && \text{if } vbinop_{sh}(c_1, c_2) = \epsilon \end{aligned}$$

sh.ternop

1. Assert: Due to **validation**, a value of **vector type v128** is on the top of the stack.

2. Pop the value $(v128.const\ c_3)$ from the stack.

3. Assert: Due to **validation**, a value of **vector type v128** is on the top of the stack.

4. Pop the value $(v128.const\ c_2)$ from the stack.

5. Assert: Due to **validation**, a value of **vector type v128** is on the top of the stack.

6. Pop the value $(v128.const\ c_1)$ from the stack.

7. If $ternop_{sh}(c_1, c_2, c_3)$ is empty, then:

a. Trap.

8. Let c be an element of $ternop_{sh}(c_1, c_2, c_3)$.

9. Push the value $(v128.const\ c)$ to the stack.

$$\begin{aligned} (v128.const\ c_1)\ (v128.const\ c_2)\ (v128.const\ c_3)\ (sh.ternop) &\hookrightarrow (v128.const\ c) && \text{if } c \in ternop_{sh}(c_1, c_2, c_3) \\ (v128.const\ c_1)\ (v128.const\ c_2)\ (v128.const\ c_3)\ (sh.ternop) &\hookrightarrow \text{trap} && \text{if } ternop_{sh}(c_1, c_2, c_3) = \epsilon \end{aligned}$$

sh.vtestop

1. Assert: Due to **validation**, a value of **vector type v128** is on the top of the stack.

2. Pop the value $(v128.const\ c_1)$ from the stack.

3. Let i be $vtestop_{sh}(c_1)$.

4. Push the value $(i32.const\ i)$ to the stack.

$$(v128.const\ c_1)\ (sh.vtestop) \hookrightarrow (i32.const\ i) \quad \text{if } i = vtestop_{sh}(c_1)$$

sh.vrelop

1. Assert: Due to **validation**, a value of **vector type v128** is on the top of the stack.

2. Pop the value $(v128.const\ c_2)$ from the stack.

3. Assert: Due to **validation**, a value of **vector type v128** is on the top of the stack.

4. Pop the value $(v128.const\ c_1)$ from the stack.

5. Let c be $vrelop_{sh}(c_1, c_2)$.

6. Push the value $(v128.const\ c)$ to the stack.

$$(v128.const\ c_1)\ (v128.const\ c_2)\ (sh.vrelop) \hookrightarrow (v128.const\ c) \quad \text{if } c = vrelop_{sh}(c_1, c_2)$$

sh.vshiftp

1. Assert: Due to **validation**, a value of **number type i32** is on the top of the stack.

2. Pop the value $(i32.const\ i)$ from the stack.

3. Assert: Due to **validation**, a value of **vector type v128** is on the top of the stack.

4. Pop the value $(v128.const\ c_1)$ from the stack.

5. Let c be $vshiftp_{sh}(c_1, i)$.

6. Push the value $(v128.\text{const } c)$ to the stack.

$$(v128.\text{const } c_1) (i32.\text{const } i) (sh.vshiftop) \hookrightarrow (v128.\text{const } c) \text{ if } c = vshiftop_{sh}(c_1, i)$$

sh.bitmask

1. Assert: Due to [validation](#), a value of [vector type v128](#) is on the top of the stack.
2. Pop the value $(v128.\text{const } c_1)$ from the stack.
3. Let c be $\text{bitmask}_{sh}(c_1)$.
4. Push the value $(i32.\text{const } c)$ to the stack.

$$(v128.\text{const } c_1) (sh.\text{bitmask}) \hookrightarrow (i32.\text{const } c) \text{ if } c = \text{bitmask}_{sh}(c_1)$$

sh.swizzlop

1. Assert: Due to [validation](#), a value of [vector type v128](#) is on the top of the stack.
2. Pop the value $(v128.\text{const } c_2)$ from the stack.
3. Assert: Due to [validation](#), a value of [vector type v128](#) is on the top of the stack.
4. Pop the value $(v128.\text{const } c_1)$ from the stack.
5. Let c be $\text{swizzlop}_{sh}(c_1, c_2)$.
6. Push the value $(v128.\text{const } c)$ to the stack.

$$(v128.\text{const } c_1) (v128.\text{const } c_2) (sh.\text{swizzlop}) \hookrightarrow (v128.\text{const } c) \text{ if } c = \text{swizzlop}_{sh}(c_1, c_2)$$

*sh.shuffle i**

1. Assert: Due to [validation](#), a value of [vector type v128](#) is on the top of the stack.
2. Pop the value $(v128.\text{const } c_2)$ from the stack.
3. Assert: Due to [validation](#), a value of [vector type v128](#) is on the top of the stack.
4. Pop the value $(v128.\text{const } c_1)$ from the stack.
5. Let c be $\text{shuffle}_{sh}(i^*, c_1, c_2)$.
6. Push the value $(v128.\text{const } c)$ to the stack.

$$(v128.\text{const } c_1) (v128.\text{const } c_2) (sh.\text{shuffle } i^*) \hookrightarrow (v128.\text{const } c) \text{ if } c = \text{shuffle}_{sh}(i^*, c_1, c_2)$$

iN×M.splat

1. Assert: Due to [validation](#), a value is on the top of the stack.
2. Pop the value $(numtype_0.\text{const } c_1)$ from the stack.
3. Assert: Due to [validation](#), $numtype_0 = \text{unpack}(iN)$.
4. Let c be $\text{lanes}_{iN \times M}^{-1}(\text{pack}_{iN}(c_1)^M)$.
5. Push the value $(v128.\text{const } c)$ to the stack.

$$(\text{unpack}(iN).\text{const } c_1) (iN \times M.\text{splat}) \hookrightarrow (v128.\text{const } c) \text{ if } c = \text{lanes}_{iN \times M}^{-1}(\text{pack}_{iN}(c_1)^M)$$

lanetype $\times M$.extract_lane_ sx' ? i

1. Assert: Due to **validation**, a value of **vector type** v128 is on the top of the stack.
 2. Pop the value ($v128.\text{const } c_1$) from the stack.
 3. If sx' ? is not defined, then:
 - a. Assert: Due to **validation**, *lanetype* is number type.
 - b. Assert: Due to **validation**, $i < |\text{lanes}_{\text{lanetype} \times M}(c_1)|$.
 - c. Let c_2 be $\text{lanes}_{\text{lanetype} \times M}(c_1)[i]$.
 - d. Push the value (*lanetype*.const c_2) to the stack.
 4. Else:
 - a. Assert: Due to **validation**, *lanetype* is packed type.
 - b. Let sx be sx' ?
 - c. Assert: Due to **validation**, $i < |\text{lanes}_{\text{lanetype} \times M}(c_1)|$.
 - d. Let c_2 be $\text{extend}_{|\text{lanetype}|, 32}^{sx}(\text{lanes}_{\text{lanetype} \times M}(c_1)[i])$.
 - e. Push the value ($i32.\text{const } c_2$) to the stack.
- $$\begin{aligned}

 \end{aligned}$$

sh_2 .vextunop_ sh_1

1. Assert: Due to **validation**, a value of **vector type** v128 is on the top of the stack.
 2. Pop the value ($v128.\text{const } c_1$) from the stack.
 3. Let c be $vextunop_{sh_1, sh_2}(c_1)$.
 4. Push the value ($v128.\text{const } c$) to the stack.
- $$(v128.\text{const } c_1) (sh_2.vextunop_{sh_1}) \hookrightarrow (v128.\text{const } c) \quad \text{if } vextunop_{sh_1, sh_2}(c_1) = c$$

sh_2 .vextbinop_ sh_1

1. Assert: Due to **validation**, a value of **vector type** v128 is on the top of the stack.
2. Pop the value ($v128.\text{const } c_2$) from the stack.
3. Assert: Due to **validation**, a value of **vector type** v128 is on the top of the stack.
4. Pop the value ($v128.\text{const } c_1$) from the stack.
5. Let c be $vextbinop_{sh_1, sh_2}(c_1, c_2)$.

6. Push the value $(\text{v128.const } c)$ to the stack.

$$(\text{v128.const } c_1) (\text{v128.const } c_2) (sh_2.\text{vextbinop_sh}_1) \hookrightarrow (\text{v128.const } c) \text{ if } \text{vextbinop}_{sh_1, sh_2}(c_1, c_2) = c$$

$sh_2.\text{vextternop_sh}_1$

1. Assert: Due to [validation](#), a value of [vector type v128](#) is on the top of the stack.
2. Pop the value $(\text{v128.const } c_3)$ from the stack.
3. Assert: Due to [validation](#), a value of [vector type v128](#) is on the top of the stack.
4. Pop the value $(\text{v128.const } c_2)$ from the stack.
5. Assert: Due to [validation](#), a value of [vector type v128](#) is on the top of the stack.
6. Pop the value $(\text{v128.const } c_1)$ from the stack.
7. Let c be $\text{vextternop}_{sh_1, sh_2}(c_1, c_2, c_3)$.
8. Push the value $(\text{v128.const } c)$ to the stack.

$$(\text{v128.const } c_1) (\text{v128.const } c_2) (\text{v128.const } c_3) (sh_2.\text{vextternop_sh}_1) \hookrightarrow (\text{v128.const } c) \text{ if } \text{vextternop}_{sh_1, sh_2}(c_1, c_2, c_3) = c$$

$sh_2.\text{narrow_sh}_1\text{sx}$

1. Assert: Due to [validation](#), a value of [vector type v128](#) is on the top of the stack.
2. Pop the value $(\text{v128.const } c_2)$ from the stack.
3. Assert: Due to [validation](#), a value of [vector type v128](#) is on the top of the stack.
4. Pop the value $(\text{v128.const } c_1)$ from the stack.
5. Let c be $\text{narrow}_{sh_1, sh_2}^{sx}(c_1, c_2)$.
6. Push the value $(\text{v128.const } c)$ to the stack.

$$(\text{v128.const } c_1) (\text{v128.const } c_2) (sh_2.\text{narrow_sh}_1\text{sx}) \hookrightarrow (\text{v128.const } c) \text{ if } c = \text{narrow}_{sh_1, sh_2}^{sx}(c_1, c_2)$$

$sh_2.\text{vcvtop_sh}_1$

1. Assert: Due to [validation](#), a value of [vector type v128](#) is on the top of the stack.
2. Pop the value $(\text{v128.const } c_1)$ from the stack.
3. Let c be $\text{vcvtop}_{sh_1, sh_2}(\text{vcvtop}, c_1)$.
4. Push the value $(\text{v128.const } c)$ to the stack.

$$(\text{v128.const } c_1) (sh_2.\text{vcvtop_sh}_1) \hookrightarrow (\text{v128.const } c) \text{ if } c = \text{vcvtop}_{sh_1, sh_2}(\text{vcvtop}, c_1)$$

4.6.12 Expressions

An [expression](#) is *evaluated* relative to a [current frame](#) pointing to its containing [module instance](#).

$\text{eval_expr } instr^*$

1. Execute the sequence $instr^*$.
2. Pop the value val from the stack.
3. Return val .

$$z; instr^* \hookrightarrow^* z'; val^* \text{ if } z; instr^* \hookrightarrow^* z'; val^*$$

Note

Evaluation iterates this reduction rule until reaching a value. Expressions constituting **function** bodies are executed during function **invocation**.

4.7 Modules

For modules, the execution semantics primarily defines **instantiation**, which **allocates** instances for a module and its contained definitions, initializes **memories** and **tables** from contained **data** and **element** segments, and invokes the **start function** if present. It also includes **invocation** of exported functions.

4.7.1 Allocation

New instances of **tags**, **globals**, **memories**, **tables**, **functions**, **data segments**, and **element segments** are *allocated* in a **store** s , as defined by the following auxiliary functions.

Tags

$\text{alloctag}(s, \text{tagtype})$

1. Let taginst be the tag instance $\{\text{type } \text{tagtype}\}$.
2. Let a be the length of $s.\text{tags}$.
3. Append taginst to $s.\text{tags}$.
4. Return a .

$$\text{alloctag}(s, \text{tagtype}) = (s \oplus \{\text{tags } \text{taginst}\}, |s.\text{tags}|) \\ \text{if } \text{taginst} = \{\text{type } \text{tagtype}\}$$

Globals

$\text{allocglobal}(s, \text{globaltype}, \text{val})$

1. Let globalinst be the global instance $\{\text{type } \text{globaltype}, \text{value } \text{val}\}$.
2. Let a be the length of $s.\text{globals}$.
3. Append globalinst to $s.\text{globals}$.
4. Return a .

$$\text{allocglobal}(s, \text{globaltype}, \text{val}) = (s \oplus \{\text{globals } \text{globalinst}\}, |s.\text{globals}|) \\ \text{if } \text{globalinst} = \{\text{type } \text{globaltype}, \text{value } \text{val}\}$$

Memories

$\text{allocmem}(s, \text{at } [i..j] \text{ page})$

1. Let meminst be the memory instance $\{\text{type } (\text{at } [i..j] \text{ page}), \text{bytes } 0\text{x}00^{i \cdot 64 \text{ Ki}}\}$.
2. Let a be the length of $s.\text{mems}$.
3. Append meminst to $s.\text{mems}$.
4. Return a .

$$\text{allocmem}(s, \text{at } [i..j] \text{ page}) = (s \oplus \{\text{mems } \text{meminst}\}, |s.\text{mems}|) \\ \text{if } \text{meminst} = \{\text{type } (\text{at } [i..j] \text{ page}), \text{bytes } (0\text{x}00)^{i \cdot 64 \text{ Ki}}\}$$

Tables

$\text{allocatable}(s, at [i..j] rt, ref)$

1. Let $tableinst$ be the table instance $\{\text{type } (at [i..j] rt), \text{elem } ref^i\}$.
2. Let a be the length of $s.tables$.
3. Append $tableinst$ to $s.tables$.
4. Return a .

$$\begin{aligned} \text{allocatable}(s, at [i..j] rt, ref) &= (s \oplus \{\text{tables } tableinst\}, |s.tables|) \\ \text{if } tableinst &= \{\text{type } (at [i..j] rt), \text{elem } ref^i\} \end{aligned}$$

Functions

$\text{allocfunc}(s, deftype, code, moduleinst)$

1. Let $funcinst$ be the function instance $\{\text{type } deftype, \text{module } moduleinst, \text{code } code\}$.
2. Let a be the length of $s.funcs$.
3. Append $funcinst$ to $s.funcs$.
4. Return a .

$$\begin{aligned} \text{allocfunc}(s, deftype, code, moduleinst) &= (s \oplus \{\text{funcs } funcinst\}, |s.funcs|) \\ \text{if } funcinst &= \{\text{type } deftype, \text{module } moduleinst, \text{code } code\} \end{aligned}$$

Data segments

$\text{allocdata}(s, ok, byte^*)$

1. Let $datainst$ be the data instance $\{\text{bytes } byte^*\}$.
2. Let a be the length of $s.datas$.
3. Append $datainst$ to $s.datas$.
4. Return a .

$$\begin{aligned} \text{allocdata}(s, ok, byte^*) &= (s \oplus \{\text{datas } datainst\}, |s.datas|) \\ \text{if } datainst &= \{\text{bytes } byte^*\} \end{aligned}$$

Element segments

$\text{allocelem}(s, elemtype, ref^*)$

1. Let $eleminst$ be the element instance $\{\text{type } elemtype, \text{elem } ref^*\}$.
2. Let a be the length of $s.elems$.
3. Append $eleminst$ to $s.elems$.
4. Return a .

$$\begin{aligned} \text{allocelem}(s, elemtype, ref^*) &= (s \oplus \{\text{elems } eleminst\}, |s.elems|) \\ \text{if } eleminst &= \{\text{type } elemtype, \text{elem } ref^*\} \end{aligned}$$

Growing memories

$\text{growmem}(\text{meminst}, n)$

1. Let $\{\text{type}(\text{at } [i \dots j] \text{ page}), \text{bytes } b^*\}$ be the destructuring of meminst .
2. If $|b^*|/(64 \text{ Ki}) + n > j$, then:
 - a. Fail.
3. Let i' be $|b^*|/(64 \text{ Ki}) + n$.
4. Let $\text{meminst}'$ be the memory instance $\{\text{type}(\text{at } [i' \dots j] \text{ page}), \text{bytes } b^* \text{ 0x00}^{n \cdot 64 \text{ Ki}}\}$.
5. Return $\text{meminst}'$.

$$\text{growmem}(\text{meminst}, n) = \text{meminst}' \quad \begin{array}{l} \text{if } \text{meminst} = \{\text{type}(\text{at } [i \dots j] \text{ page}), \text{bytes } b^*\} \\ \wedge \text{meminst}' = \{\text{type}(\text{at } [i' \dots j] \text{ page}), \text{bytes } b^* \text{ (0x00)}^{n \cdot 64 \text{ Ki}}\} \\ \wedge i' = |b^*|/(64 \text{ Ki}) + n \leq j \end{array}$$

Growing tables

$\text{growtable}(\text{tableinst}, n, r)$

1. Let $\{\text{type}(\text{at } [i \dots j] \text{ rt}), \text{elem } r'^*\}$ be the destructuring of tableinst .
2. If $|r'^*| + n > j$, then:
 - a. Fail.
3. Let i' be $|r'^*| + n$.
4. Let $\text{tableinst}'$ be the table instance $\{\text{type}(\text{at } [i' \dots j] \text{ rt}), \text{elem } r'^* r^n\}$.
5. Return $\text{tableinst}'$.

$$\text{growtable}(\text{tableinst}, n, r) = \text{tableinst}' \quad \begin{array}{l} \text{if } \text{tableinst} = \{\text{type}(\text{at } [i \dots j] \text{ rt}), \text{elem } r'^*\} \\ \wedge \text{tableinst}' = \{\text{type}(\text{at } [i' \dots j] \text{ rt}), \text{elem } r'^* r^n\} \\ \wedge i' = |r'^*| + n \leq j \end{array}$$

Modules

$\text{allocmodule}(s, \text{module}, \text{externaddr}^*, \text{val}_g^*, \text{ref}_t^*, \text{ref}_e^*)$

1. Let $(\text{module type}^* \text{ import}^* \text{ tag}^* \text{ global}^* \text{ mem}^* \text{ table}^* \text{ func}^* \text{ data}^* \text{ elem}^* \text{ start}^? \text{ export}^*)$ be the destructuring of module .
2. Let aa_i^* be $\text{tags}(\text{externaddr}^*)$.
3. Let ga_i^* be $\text{globals}(\text{externaddr}^*)$.
4. Let fa_i^* be $\text{funcs}(\text{externaddr}^*)$.
5. Let ma_i^* be $\text{mems}(\text{externaddr}^*)$.
6. Let ta_i^* be $\text{tables}(\text{externaddr}^*)$.
7. Let fa^* be $|s.\text{funcs}| + i_f$ for all i_f from 0 to $|func^*| - 1$.
8. Let $(\text{tag } \text{tagtype})^*$ be tag^* .
9. Let $(\text{data } \text{byte}^* \text{ datamode})^*$ be data^* .
10. Let $(\text{global } \text{globaltype } \text{expr}_g)^*$ be global^* .
11. Let $(\text{table } \text{tabletype } \text{expr}_t)^*$ be table^* .
12. Let $(\text{memory } \text{memtype})^*$ be mem^* .
13. Let dt^* be $\text{alloctype}^*(\text{type}^*)$.
14. Let $(\text{elem } \text{elemtype } \text{expr}_e^* \text{ elemmode})^*$ be elem^* .

15. Let $(\text{func } x \text{ local}^* \text{ expr}_f)^*$ be func^* .
16. Let aa^* be ϵ .
17. For each tagtype in tagtype^* , do:
 - a. Let aa be the **tag address** `alloctag`($s, \text{tagtype}[:, dt^*]$).
 - b. Append aa to aa^* .
18. Let ga^* be ϵ .
19. For each globaltype in globaltype^* and val_g in val_g^* , do:
 - a. Let ga be the **global address** `allocglobal`($s, \text{globaltype}[:, dt^*], \text{val}_g$).
 - b. Append ga to ga^* .
20. Let ma^* be ϵ .
21. For each memtype in memtype^* , do:
 - a. Let ma be the **memory address** `allocmem`($s, \text{memtype}[:, dt^*]$).
 - b. Append ma to ma^* .
22. Let ta^* be ϵ .
23. For each tabletype in tabletype^* and ref_t in ref_t^* , do:
 - a. Let ta be the **table address** `alloctable`($s, \text{tabletype}[:, dt^*], \text{ref}_t$).
 - b. Append ta to ta^* .
24. Let xi^* be ϵ .
25. For each export in export^* , do:
 - a. Let xi be the **export instance** `allocexport`($\text{moduleinst}, \text{export}$).
 - b. Append xi to xi^* .
26. Let da^* be ϵ .
27. For each byte^* in byte^{**} , do:
 - a. Let da be the **data address** `allocdata`($s, \text{ok}, \text{byte}^*$).
 - b. Append da to da^* .
28. Let ea^* be ϵ .
29. For each elemtype in elemtype^* and ref_e in ref_e^{**} , do:
 - a. Let ea be the **elem address** `allocelem`($s, \text{elemtype}[:, dt^*], \text{ref}_e^*$).
 - b. Append ea to ea^* .
30. Let moduleinst be the **module instance** $\{\text{types } dt^*, \text{tags } aa_i^* aa^*, \text{globals } ga_i^* ga^*, \text{mems } ma_i^* ma^*, \text{tables } ta_i^* ta^*, \text{funcs } \dots\}$.
31. Let funcaddr_0^* be ϵ .
32. For each expr_f in expr_f^* and local^* in local^{**} and x in x^* , do:
 - a. Let funcaddr_0 be the **function address** `allocfunc`($s, dt^*[x], \text{func } x \text{ local}^* \text{ expr}_f, \text{moduleinst}$).
 - b. Append funcaddr_0 to funcaddr_0^* .
33. Assert: Due to validation, $\text{funcaddr}_0^* = fa^*$.
34. Return moduleinst .

$\text{allocmodule}(s, \text{module}, \text{externaddr}^*, \text{val}_g^*, \text{ref}_t^*, (\text{ref}_e^*)^*) = (s_7, \text{moduleinst})$
 $\text{if } \text{module} = \text{module type}^* \text{ import}^* \text{ tag}^* \text{ global}^* \text{ mem}^* \text{ table}^* \text{ func}^* \text{ data}^* \text{ elem}^* \text{ start}^? \text{ export}^*$
 $\wedge \text{tag}^* = (\text{tag } \text{tagtype})^*$
 $\wedge \text{global}^* = (\text{global } \text{globaltype } \text{expr}_g)^*$
 $\wedge \text{mem}^* = (\text{memory } \text{memtype})^*$
 $\wedge \text{table}^* = (\text{table } \text{tabletype } \text{expr}_t)^*$
 $\wedge \text{func}^* = (\text{func } x \text{ local}^* \text{ expr}_f)^*$
 $\wedge \text{data}^* = (\text{data } \text{byte}^* \text{ datamode})^*$
 $\wedge \text{elem}^* = (\text{elem } \text{elemtype } \text{expr}_e^* \text{ elemmode})^*$
 $\wedge \text{aa}_i^* = \text{tags}(\text{externaddr}^*)$
 $\wedge \text{ga}_i^* = \text{globals}(\text{externaddr}^*)$
 $\wedge \text{ma}_i^* = \text{mems}(\text{externaddr}^*)$
 $\wedge \text{ta}_i^* = \text{tables}(\text{externaddr}^*)$
 $\wedge \text{fa}_i^* = \text{funcs}(\text{externaddr}^*)$
 $\wedge \text{dt}^* = \text{alloctype}^*(\text{type}^*)$
 $\wedge \text{fa}^* = (|s.\text{funcs}| + i_f)^{i_f < |func^*|}$
 $\wedge (s_1, \text{aa}^*) = \text{alloc}^*(s, \text{tagtype}[:=\text{dt}^*])^*$
 $\wedge (s_2, \text{ga}^*) = \text{alloc}^*(s_1, \text{globaltype}[:=\text{dt}^*], \text{val}_g^*)$
 $\wedge (s_3, \text{ma}^*) = \text{alloc}^*(s_2, \text{memtype}[:=\text{dt}^*])^*$
 $\wedge (s_4, \text{ta}^*) = \text{alloc}^*(s_3, \text{tabletype}[:=\text{dt}^*], \text{ref}_t^*)$
 $\wedge (s_5, \text{da}^*) = \text{alloc}^*(s_4, \text{ok}^{|\text{data}^*|}, (\text{byte}^*)^*)$
 $\wedge (s_6, \text{ea}^*) = \text{alloc}^*(s_5, \text{elemtype}[:=\text{dt}^*], (\text{ref}_e^*)^*)$
 $\wedge (s_7, \text{fa}^*) = \text{alloc}^*(s_6, \text{dt}^*[x]^*, (\text{func } x \text{ local}^* \text{ expr}_f)^*, \text{moduleinst}^{|\text{func}^*|})$
 $\wedge \text{xi}^* = \text{alloc}^*(\{\text{tags } \text{aa}_i^* \text{ aa}^*, \text{globals } \text{ga}_i^* \text{ ga}^*, \text{mems } \text{ma}_i^* \text{ ma}^*, \text{tables } \text{ta}_i^* \text{ ta}^*, \text{funcs } \text{fa}_i^* \text{ fa}^*\}, \text{export}^*)$
 $\wedge \text{moduleinst} = \{\text{types } \text{dt}^*,$
 $\quad \text{tags } \text{aa}_i^* \text{ aa}^*, \text{globals } \text{ga}_i^* \text{ ga}^*,$
 $\quad \text{mems } \text{ma}_i^* \text{ ma}^*,$
 $\quad \text{tables } \text{ta}_i^* \text{ ta}^*, \text{funcs } \text{fa}_i^* \text{ fa}^*, \text{datas } \text{da}^*,$
 $\quad \text{elems } \text{ea}^*, \text{exports } \text{xi}^*\}$

Here, the notation allocx^* is shorthand for multiple [allocations](#) of object kind X , defined as follows:

$$\begin{aligned}
 \text{allocX}^*(s, \epsilon, \epsilon) &= (s, \epsilon) \\
 \text{allocX}^*(s, X \text{ } X'^*, Y \text{ } Y'^*) &= (s_2, a \text{ } a'^*) \quad \text{if } (s_1, a) = \text{allocX}(X, Y, s, X, Y) \\
 &\quad \wedge (s_2, a'^*) = \text{allocX}^*(s_1, X'^*, Y'^*)
 \end{aligned}$$

For types, however, allocation is defined in terms of [rolling](#) and [substitution](#) of all preceding types to produce a list of [closed defined types](#):

$\text{alloytype}^*(\text{type}''^*)$

1. If $\text{type}''^* = \epsilon$, then:
 - a. Return ϵ .
2. Let $\text{type}'^* \text{ type}$ be type''^* .
3. Let $(\text{type } \text{rectype})$ be the destructuring of type .
4. Let $\text{deftype}'^*$ be $\text{alloytype}^*(\text{type}'^*)$.
5. Let x be the length of $\text{deftype}'^*$.
6. Let deftype^* be $\text{roll}_x^*(\text{rectype})[:=\text{deftype}'^*]$.
7. Return $\text{deftype}'^* \text{ defeotype}^*$.

$$\begin{aligned}
 \text{alloytype}^*(\epsilon) &= \epsilon \\
 \text{alloytype}^*(\text{type}'^* \text{ type}) &= \text{deftype}'^* \text{ defeotype}^* \quad \text{if } \text{deftype}'^* = \text{alloytype}^*(\text{type}'^*) \\
 &\quad \wedge \text{type} = \text{type } \text{rectype} \\
 &\quad \wedge \text{deftype}^* = \text{roll}_x^*(\text{rectype})[:=\text{deftype}'^*] \\
 &\quad \wedge x = |\text{deftype}'^*|
 \end{aligned}$$

Finally, export instances are produced with the help of the following definition:

`allocexport(moduleinst, export name externidx)`

1. If *externidx* is some tag *tagidx*, then:
 - a. Let (tag *x*) be the destructuring of *externidx*.
 - b. Return {name *name*, addr (tag *moduleinst*.tags[*x*])}.
2. If *externidx* is some global *globalidx*, then:
 - a. Let (global *x*) be the destructuring of *externidx*.
 - b. Return {name *name*, addr (global *moduleinst*.globals[*x*])}.
3. If *externidx* is some memory *memidx*, then:
 - a. Let (memory *x*) be the destructuring of *externidx*.
 - b. Return {name *name*, addr (mem *moduleinst*.mems[*x*])}.
4. If *externidx* is some table *tableidx*, then:
 - a. Let (table *x*) be the destructuring of *externidx*.
 - b. Return {name *name*, addr (table *moduleinst*.tables[*x*])}.
5. Assert: Due to validation, *externidx* is some func *funcidx*.
6. Let (func *x*) be the destructuring of *externidx*.
7. Return {name *name*, addr (func *moduleinst*.funcs[*x*])}.

<code>allocexport(moduleinst, export name (tag <i>x</i>))</code>	<code>= {name <i>name</i>, addr (tag <i>moduleinst</i>.tags[<i>x</i>])}</code>
<code>allocexport(moduleinst, export name (global <i>x</i>))</code>	<code>= {name <i>name</i>, addr (global <i>moduleinst</i>.globals[<i>x</i>])}</code>
<code>allocexport(moduleinst, export name (memory <i>x</i>))</code>	<code>= {name <i>name</i>, addr (mem <i>moduleinst</i>.mems[<i>x</i>])}</code>
<code>allocexport(moduleinst, export name (table <i>x</i>))</code>	<code>= {name <i>name</i>, addr (table <i>moduleinst</i>.tables[<i>x</i>])}</code>
<code>allocexport(moduleinst, export name (func <i>x</i>))</code>	<code>= {name <i>name</i>, addr (func <i>moduleinst</i>.funcs[<i>x</i>])}</code>

Note

The definition of module allocation is mutually recursive with the allocation of its associated functions, because the resulting module instance is passed to the allocators as an argument, in order to form the necessary closures. In an implementation, this recursion is easily unraveled by mutating one or the other in a secondary step.

4.7.2 Instantiation

Given a store *s*, a *module* is instantiated with a list of external addresses *externaddr*^{*} supplying the required imports as follows.

Instantiation checks that the module is *valid* and the provided imports *match* the declared types, and may *fail* with an error otherwise. Instantiation can also result in an *exception* or *trap* when initializing a *table* or *memory* from an *active segment* or when executing the *start* function. It is up to the *embedder* to define how such conditions are reported.

`instantiate(s, module, externaddr*)`

1. If *module* is not *valid*, then:
 - a. Fail.
2. Let *xt*_i^{*} → *xt*_e^{*} be the destructuring of the type of *module*.
3. Let (module *type*^{*} *import*^{*} *tag*^{*} *global*^{*} *mem*^{*} *table*^{*} *func*^{*} *data*^{*} *elem*^{*} *start*[?] *export*^{*}) be the destructuring of *module*.
4. If |*externaddr*^{*}| ≠ |*xt*_i^{*}|, then:
 - a. Fail.

5. For all *externaddr* in *externaddr*^{*}, and corresponding *xt_i* in *xt_i*^{*}:
 - a. If *externaddr* is not valid with type *xt_i*, then:
 - 1) Fail.
6. Let *instr_d*^{*} be the concatenation of *rundata_{id}*(*data*^{*}[*i_d*])^{*i_d* < |*data*^{*}|}.
7. Let *instr_e*^{*} be the concatenation of *runelem_{ie}*(*elem*^{*}[*i_e*])^{*i_e* < |*elem*^{*}|}.
8. Let *moduleinst₀* be the module instance {types *alloctype*^{*}(*type*^{*}), globals *globals*(*externaddr*^{*}), funcs *funcs*(*externaddr*^{*})
9. Let (table *tabletype* *expr_t*)^{*} be *table*^{*}.
10. Let (global *globaltype* *expr_g*)^{*} be *global*^{*}.
11. Let (elem *reftype* *expr_e*^{*} *elemmode*)^{*} be *elem*^{*}.
12. Let *z* be the state (*s*, {module *moduleinst₀*}).
13. Let *F* be the frame *z.frame*.
14. Push the frame *F*.
15. Let *val_g*^{*} be *evalglobal*^{*}(*z*, *globaltype*^{*}, *expr_g*^{*}).
16. Pop the frame *f* from the stack.
17. Let *f* be the frame *f*.
18. Push the frame *F*.
19. Let *ref_t*^{*} be the result of evaluating *expr_t*^{*} with state *z*.
20. Pop the frame *f* from the stack.
21. Let *f* be the frame *f*.
22. Push the frame *F*.
23. Let *ref_e*^{**} be the result of evaluating *expr_e*^{**} with state *z*.
24. Pop the frame *f* from the stack.
25. Let *moduleinst* be *allocmodule*(*s*, *module*, *externaddr*^{*}, *val_g*^{*}, *ref_t*^{*}, *ref_e*^{**}).
26. Let *F* be the frame {module *moduleinst*}.
27. Push the frame *F*.
28. Execute the sequence *instr_e*^{*}.
29. Execute the sequence *instr_d*^{*}.
30. If *start*[?] is defined, then:
 - a. Let (start *x*) be *start*[?].
 - b. Let *instr_s* be the instruction (call *x*).
 - c. Execute the instruction *instr_s*.
31. Pop the frame *F* from the stack.
32. Return {module *moduleinst*}^{*}.module.

$$\begin{aligned}
 \text{instantiate}(s, \text{module}, \text{externaddr}^*) &= s'; \{ \text{module } \text{moduleinst} \}; \text{instr}_e^* \text{instr}_d^* \text{instr}_s^? \\
 &\text{if } \vdash \text{module} : \text{xt}_i^* \rightarrow \text{xt}_e^* \\
 &\wedge (s \vdash \text{externaddr} : \text{xt}_i)^* \\
 &\wedge \text{module} = \text{module type}^* \text{import}^* \text{tag}^* \text{global}^* \text{mem}^* \text{table}^* \text{func}^* \text{data}^* \text{elem}^* \text{start}^? \text{export}^* \\
 &\wedge \text{global}^* = (\text{global } \text{globaltype } \text{expr}_g^*)^* \\
 &\wedge \text{table}^* = (\text{table } \text{tabletype } \text{expr}_t^*)^* \\
 &\wedge \text{data}^* = (\text{data } \text{byte}^* \text{datamode})^* \\
 &\wedge \text{elem}^* = (\text{elem } \text{reftype } \text{expr}_e^* \text{elemmode})^* \\
 &\wedge \text{start}^? = (\text{start } x)^? \\
 &\wedge \text{moduleinst}_0 = \{ \text{types } \text{alloctype}^*(\text{type}^*), \\
 &\quad \text{globals } \text{globals}(\text{externaddr}^*), \\
 &\quad \text{funcs } \text{funcs}(\text{externaddr}^*) (|s.\text{funcs}| + i_f)^{i_f < |\text{func}^*|} \} \\
 &\wedge z = s; \{ \text{module } \text{moduleinst}_0 \} \\
 &\wedge (z', \text{val}_g^*) = \text{evalglobal}^*(z, \text{globaltype}^*, \text{expr}_g^*) \\
 &\wedge (z'; \text{expr}_t \hookrightarrow^* z'; \text{ref}_t)^* \\
 &\wedge (z'; \text{expr}_e \hookrightarrow^* z'; \text{ref}_e)^{**} \\
 &\wedge (s', \text{moduleinst}) = \text{allocmodule}(s, \text{module}, \text{externaddr}^*, \text{val}_g^*, \text{ref}_t^*, (\text{ref}_e^*)^*) \\
 &\wedge \text{instr}_d^* = \bigoplus \text{rundata}_{i_d}(\text{data}^*[i_d])^{i_d < |\text{data}^*|} \\
 &\wedge \text{instr}_e^* = \bigoplus \text{runelem}_{i_e}(\text{elem}^*[i_e])^{i_e < |\text{elem}^*|} \\
 &\wedge \text{instr}_s^? = (\text{call } x)^?
 \end{aligned}$$

where:

$\text{evalglobal}^*(z, \text{globaltype}^*, \text{expr}''^*)$

1. If $\text{expr}''^* = \epsilon$, then:
 - a. Assert: Due to validation, $\text{globaltype}^* = \epsilon$.
 - b. Return ϵ .
2. Else:
 - a. Let $\text{expr } \text{expr}'^*$ be expr''^* .
 - b. Assert: Due to validation, $|\text{globaltype}^*| \geq 1$.
 - c. Let $gt \text{ } gt'^*$ be globaltype^* .
 - d. Let (s, f) be the destructuring of z .
 - e. Let val be the result of evaluating expr with state z .
 - f. Let a be $\text{allocglobal}(s, gt, \text{val})$.
 - g. Append a to $f.\text{module.globals}$.
 - h. Let val'^* be $\text{evalglobal}^*((s, f), gt'^*, \text{expr}'^*)$.
 - i. Return $\text{val } \text{val}'^*$.

$$\begin{aligned}
 \text{evalglobal}^*(z, \epsilon, \epsilon) &= (z, \epsilon) \\
 \text{evalglobal}^*(z, gt \text{ } gt'^*, \text{expr } \text{expr}'^*) &= (z', \text{val } \text{val}'^*) \\
 &\quad \text{if } z; \text{expr} \hookrightarrow^* z; \text{val} \\
 &\quad \wedge z = s; f \\
 &\quad \wedge (s', a) = \text{allocglobal}(s, gt, \text{val}) \\
 &\quad \wedge (z', \text{val}'^*) = \text{evalglobal}^*((s'; f[\text{module.globals} = \oplus a]), gt'^*, \text{expr}'^*)
 \end{aligned}$$

$\text{rundata}_x(\text{data } b^n \text{ datamode})$

1. If $\text{datamode} = \text{passive}$, then:
 - a. Return ϵ .
2. Assert: Due to validation, datamode is some active $\text{memidx } \text{expr}$.
3. Let $(\text{active } y \text{ } \text{instr}^*)$ be the destructuring of datamode .

4. Return $instr^* (i32.const\ 0) (i32.const\ n) (memory.init\ y\ x) (data.drop\ x)$.

$runelem_x(elem\ rt\ e^n\ elemmode)$

1. If $elemmode = \text{passive}$, then:
 - a. Return ϵ .
2. If $elemmode = \text{declare}$, then:
 - a. Return $(elem.drop\ x)$.
3. Assert: Due to validation, $elemmode$ is some active $tableidx\ expr$.
4. Let $(active\ y\ instr^*)$ be the destructuring of $elemmode$.
5. Return $instr^* (i32.const\ 0) (i32.const\ n) (table.init\ y\ x) (elem.drop\ x)$.

$$\begin{aligned} rundata_x(data\ b^n\ (\text{passive})) &= \epsilon \\ rundata_x(data\ b^n\ (\text{active}\ y\ instr^*)) &= \\ &\quad instr^* (i32.const\ 0) (i32.const\ n) (memory.init\ y\ x) (data.drop\ x) \\ runelem_x(elem\ rt\ e^n\ (\text{passive})) &= \epsilon \\ runelem_x(elem\ rt\ e^n\ (\text{declare})) &= (elem.drop\ x) \\ runelem_x(elem\ rt\ e^n\ (\text{active}\ y\ instr^*)) &= \\ &\quad instr^* (i32.const\ 0) (i32.const\ n) (table.init\ y\ x) (elem.drop\ x) \end{aligned}$$

Note

Checking import types assumes that the [module instance](#) has already been [allocated](#) to compute the respective [closed defined types](#). However, this forward reference merely is a way to simplify the specification. In practice, implementations will likely allocate or canonicalize types beforehand, when *compiling* a module, in a stage before instantiation and before imports are checked.

Similarly, module [allocation](#) and the [evaluation](#) of [global](#) and [table](#) initializers as well as [element segments](#) are mutually recursive because the global initialization [values](#) val_g^* , ref_t , and element segment contents ref_e^{**} are passed to the module allocator while depending on the module instance $moduleinst$ and store s' returned by allocation. Again, this recursion is just a specification device. In practice, the initialization values can be [determined](#) beforehand by staging module allocation such that first, the module's own [function instances](#) are pre-allocated in the store, then the initializer expressions are evaluated in order, allocating globals on the way, then the rest of the module instance is allocated, and finally the new function instances' module fields are set to that module instance. This is possible because [validation](#) ensures that initialization expressions cannot actually call a function, only take their reference.

All failure conditions are checked before any observable mutation of the store takes place. Store mutation is not atomic; it happens in individual steps that may be interleaved with other threads.

[Evaluation](#) of [constant expressions](#) does not affect the store.

4.7.3 Invocation

$invoke(s, funcaddr, val^*)$

1. Assert: Due to validation, the [expansion](#) of $s.funcs[funcaddr].type$ is some $func\ resulttype \rightarrow resulttype$.
2. Let $(func\ t_1^* \rightarrow t_2^*)$ be the destructuring of the [expansion](#) of $s.funcs[funcaddr].type$.
3. If $|t_1^*| \neq |val^*|$, then:
 - a. Fail.
4. For all t_1 in t_1^* , and corresponding val in val^* :
 - a. If val is not [valid](#) with type t_1 , then:
 - 1) Fail.

5. Let k be the length of t_2^* .
6. Let F be the frame $\{\text{module } \{\}\}$ whose arity is k .
7. Push the frame F .
8. Push the values val^* to the stack.
9. Push the value $(\text{ref.func } funcaddr)$ to the stack.
10. Execute the instruction $(\text{call_ref } s.\text{funcs}[funcaddr].\text{type})$.
11. Pop the values val'^k from the stack.
12. Pop the frame F from the stack.
13. Return val'^k .

Once a **module** has been **instantiated**, any exported function can be **invoked** externally via its **function address** $funcaddr$ in the **store** s and an appropriate list val^* of argument **values**.

Invocation may **fail** with an error if the arguments do not fit the **function type**. Invocation can also result in an **exception** or **trap**. It is up to the **embedder** to define how such conditions are reported.

Note

If the **embedder** API performs type checks itself, either statically or dynamically, before performing an invocation, then no failure other than traps or exceptions can occur.

The following steps are performed:

1. Assert: $S.\text{funcs}[funcaddr]$ exists.
2. Let $funcinst$ be the **function instance** $S.\text{funcs}[funcaddr]$.
3. Let $\text{func } [t_1^n] \rightarrow [t_2^m]$ be the **composite type** $\text{expand}(funcinst.\text{type})$.
4. If the length $|val^*|$ of the provided argument values is different from the number n of expected arguments, then:
 - a. Fail.
5. For each **value type** t_i in t_1^n and corresponding **value** val_i in val^* , do:
 - a. If val_i is not **valid** with value type t_i , then:
 - i. Fail.
6. Let F be the dummy **frame** $\{\text{module } \{\}, \text{locals } \epsilon\}$.
7. Push the frame F to the stack.
8. Push the values val^* to the stack.
9. **Invoke** the function instance at address $funcaddr$.

Once the function has returned, the following steps are executed:

1. Assert: due to **validation**, m **values** are on the top of the stack.
2. Pop val_{res}^m from the stack.
3. Assert: due to **validation**, the frame F is now on the top of the stack.
4. Pop the frame F from the stack.

The values val_{res}^m are returned as the results of the invocation.

$$\begin{aligned} \text{invoke}(s, funcaddr, val^*) &= s; \{\text{module } \{\}\}; val^* (\text{ref.func } funcaddr) (\text{call_ref } s.\text{funcs}[funcaddr].\text{type}) \\ &\quad \text{if } s.\text{funcs}[funcaddr].\text{type} \approx \text{func } t_1^* \rightarrow t_2^* \\ &\quad \wedge (s \vdash val : t_1)^* \end{aligned}$$

5.1 Conventions

The binary format for WebAssembly **modules** is a dense linear *encoding* of their **abstract syntax**.²⁸

The format is defined by an *attribute grammar* whose only terminal symbols are **bytes**. A byte sequence is a well-formed encoding of a module if and only if it is generated by the grammar.

Each production of this grammar has exactly one synthesized attribute: the abstract syntax that the respective byte sequence encodes. Thus, the attribute grammar implicitly defines a *decoding* function (i.e., a parsing function for the binary format).

Except for a few exceptions, the binary grammar closely mirrors the grammar of the abstract syntax.

Note

Some phrases of abstract syntax have multiple possible encodings in the binary format. For example, numbers may be encoded as if they had optional leading zeros. Implementations of decoders must support all possible alternatives; implementations of encoders can pick any allowed encoding.

The recommended extension for files containing WebAssembly modules in binary format is “.wasm” and the recommended **Media Type**²⁷ is “application/wasm”.

5.1.1 Grammar

The following conventions are adopted in defining grammar rules for the binary format. They mirror the conventions used for **abstract syntax**. In order to distinguish symbols of the binary syntax from symbols of the abstract syntax, **typewriter** font is adopted for the former.

- Terminal symbols are **bytes** expressed in hexadecimal notation: 0x0F.
- Nonterminal symbols are written in typewriter font: `valtype`, `instr`.
- B^n is a sequence of $n \geq 0$ iterations of B .
- B^* is a possibly empty sequence of iterations of B . (This is a shorthand for B^n used where n is not relevant.)

²⁸ Additional encoding layers – for example, introducing compression – may be defined on top of the basic representation defined here. However, such layers are outside the scope of the current specification.

²⁷ <https://www.iana.org/assignments/media-types/media-types.xhtml>

- $B^?$ is an optional occurrence of B . (This is a shorthand for B^n where $n \leq 1$.)
- $x:B$ denotes the same language as the nonterminal B , but also binds the variable x to the attribute synthesized for B . A pattern may also be used instead of a variable, e.g., $7:B$.
- Productions are written $\text{sym} ::= B_1 \Rightarrow A_1 \mid \dots \mid B_n \Rightarrow A_n$, where each A_i is the attribute that is synthesized for sym in the given case, usually from attribute variables bound in B_i .
- Large productions may be split into multiple definitions, indicated by ending the first one with explicit ellipses, $\text{sym} ::= B_1 \mid \dots$, and starting continuations with ellipses, $\text{sym} ::= \dots \mid B_2$.
- Some productions are augmented by side conditions in parentheses, which restrict the applicability of the production. They provide a shorthand for a combinatorial expansion of the production into many separate cases.
- If the same meta variable or non-terminal symbol appears multiple times in a production (in the syntax or in an attribute), then all those occurrences must have the same instantiation. (This is a shorthand for a side condition requiring multiple different variables to be equal.)

Note

For example, the **binary grammar** for **number types** is given as follows:

$$\begin{array}{lcl} \text{numtype} & ::= & 0x7C \Rightarrow f_{64} \\ & & | 0x7D \Rightarrow f_{32} \\ & & | 0x7E \Rightarrow i_{64} \\ & & | 0x7F \Rightarrow i_{32} \end{array}$$

Consequently, the byte 0x7F encodes the type i_{32} , 0x7E encodes the type i_{64} , and so forth. No other byte value is allowed as the encoding of a number type.

The **binary grammar** for **limits** is defined as follows:

$$\begin{array}{lcl} \text{limits}_N & ::= & 0x00 \ n:\text{u64} \Rightarrow (i_{32}, [n \dots 2^N - 1]) \\ & & | 0x01 \ n:\text{u64} \ m:\text{u64} \Rightarrow (i_{32}, [n \dots m]) \\ & & | 0x04 \ n:\text{u64} \Rightarrow (i_{64}, [n \dots 2^N - 1]) \\ & & | 0x05 \ n:\text{u64} \ m:\text{u64} \Rightarrow (i_{64}, [n \dots m]) \end{array}$$

That is, a limits pair is encoded as either the byte 0x00 followed by the encoding of a u64 value, or the byte 0x01 followed by two such encodings. The variables n and m name the attributes of the respective u64 nonterminals, which in this case are the actual **unsigned integers** those decode into. The attribute of the complete production then is the abstract syntax for the limit, expressed in terms of the former values.

The variable N is a *parameter* to the grammar symbol that can be instantiated differently at each use site. In this example, it controls the value range of the limits.

5.1.2 Auxiliary Notation

When dealing with binary encodings the following notation is also used:

- ϵ denotes the empty byte sequence.
- $||B||$ is the length of the byte sequence generated from the production B in a derivation.

5.1.3 Lists

Lists are encoded with their u32 length followed by the encoding of their element sequence.

$$\text{list}(X) ::= n:\text{u32} \ (el:X)^n \Rightarrow el^n$$

5.2 Values

5.2.1 Bytes

Bytes encode themselves.

$$\text{byte} ::= 0x00 \mid \dots \mid 0xFF$$

5.2.2 Integers

All integers are encoded using the [LEB128](#)²⁹ variable-length integer encoding, in either unsigned or signed variant.

Unsigned integers are encoded in [unsigned LEB128](#)³⁰ format. As an additional constraint, the total number of bytes encoding a uN value must not exceed $\text{ceil}(N/7)$ bytes.

$$\begin{aligned} uN &::= n:\text{byte} && \Rightarrow n && \text{if } n < 2^7 \wedge n < 2^N \\ & \mid n:\text{byte } m:\text{u}(N-7) && \Rightarrow 2^7 \cdot m + (n - 2^7) && \text{if } n \geq 2^7 \wedge N > 7 \end{aligned}$$

Signed integers are encoded in [signed LEB128](#)³¹ format, which uses a two's complement representation. As an additional constraint, the total number of bytes encoding an sN value must not exceed $\text{ceil}(N/7)$ bytes.

$$\begin{aligned} sN &::= n:\text{byte} && \Rightarrow n && \text{if } n < 2^6 \wedge n < 2^{N-1} \\ & \mid n:\text{byte} && \Rightarrow n - 2^7 && \text{if } 2^6 \leq n < 2^7 \wedge n \geq 2^7 - 2^{N-1} \\ & \mid n:\text{byte } i:\text{u}(N-7) && \Rightarrow 2^7 \cdot i + (n - 2^7) && \text{if } n \geq 2^7 \wedge N > 7 \end{aligned}$$

Uninterpreted integers are encoded as signed integers.

$$iN ::= i:sN \Rightarrow \text{signed}_N^{-1}(i)$$

Note

The side conditions $N > 7$ in the productions for non-terminal bytes of the uN and sN encodings restrict the encoding's length. However, “trailing zeros” are still allowed within these bounds. For example, `0x03` and `0x83 0x00` are both well-formed encodings for the value 3 as a *us*. Similarly, either of `0x7E` and `0xFE 0x7F` and `0xFE 0xFF 0x7F` are well-formed encodings of the value -2 as an *s16*.

The side conditions on the value n of terminal bytes further enforce that any unused bits in these bytes must be 0 for positive values and 1 for negative ones. For example, `0x83 0x10` is malformed as a *us* encoding. Similarly, both `0x83 0x3E` and `0xFF 0x7B` are malformed as *ss* encodings.

5.2.3 Floating-Point

Floating-point values are encoded directly by their [IEEE 754](#)³² (Section 3.4) bit pattern in [little endian](#)³³ byte order:

$$fN ::= b*:\text{byte}^{N/8} \Rightarrow \text{bytes}_{fN}^{-1}(b*)$$

²⁹ <https://en.wikipedia.org/wiki/LEB128>

³⁰ https://en.wikipedia.org/wiki/LEB128#Unsigned_LEB128

³¹ https://en.wikipedia.org/wiki/LEB128#Signed_LEB128

³² <https://ieeexplore.ieee.org/document/8766229>

³³ <https://en.wikipedia.org/wiki/Endianness#Little-endian>

5.2.4 Names

Names are encoded as a list of bytes containing the Unicode³⁴ (Section 3.9) UTF-8 encoding of the name's character sequence.

$$\text{name} ::= b^*.\text{list}(\text{byte}) \Rightarrow \text{name} \text{ if } \text{utf8}(\text{name}) = b^*$$

The auxiliary `utf8` function expressing this encoding is defined as follows:

$$\begin{aligned} \text{utf8}(ch^*) &= \bigoplus \text{utf8}(ch)^* \\ \text{utf8}(ch) &= b && \text{if } ch < \text{U}+80 \\ & && \wedge ch = b \\ \text{utf8}(ch) &= b_1 b_2 && \text{if } \text{U}+80 \leq ch < \text{U}+0800 \\ & && \wedge ch = 2^6 \cdot (b_1 - 0\text{x}C0) + \text{cont}(b_2) \\ \text{utf8}(ch) &= b_1 b_2 b_3 && \text{if } \text{U}+0800 \leq ch < \text{U}+\text{D}800 \vee \text{U}+\text{E}000 \leq ch < \text{U}+10000 \\ & && \wedge ch = 2^{12} \cdot (b_1 - 0\text{x}E0) + 2^6 \cdot \text{cont}(b_2) + \text{cont}(b_3) \\ \text{utf8}(ch) &= b_1 b_2 b_3 b_4 && \text{if } \text{U}+10000 \leq ch < \text{U}+11000 \\ & && \wedge ch = 2^{18} \cdot (b_1 - 0\text{x}F0) + 2^{12} \cdot \text{cont}(b_2) + 2^6 \cdot \text{cont}(b_3) + \text{cont}(b_4) \end{aligned}$$

where $\text{cont}(b) = b - 0\text{x}80$ if $(0\text{x}80 < b < 0\text{x}C0)$

Note

Unlike in some other formats, name strings are not 0-terminated.

5.3 Types

Note

In some places, possible types include both type constructors or types denoted by `type indices`. Thus, the binary format for type constructors corresponds to the encodings of small negative `sN` values, such that they can unambiguously occur in the same place as (positive) type indices.

5.3.1 Number Types

Number types are encoded by a single byte.

$$\begin{aligned} \text{numtype} ::= & \begin{array}{l} 0\text{x}7C \Rightarrow \text{f}_{64} \\ | \quad 0\text{x}7D \Rightarrow \text{f}_{32} \\ | \quad 0\text{x}7E \Rightarrow \text{i}_{64} \\ | \quad 0\text{x}7F \Rightarrow \text{i}_{32} \end{array} \end{aligned}$$

5.3.2 Vector Types

Vector types are also encoded by a single byte.

$$\text{vectype} ::= 0\text{x}7B \Rightarrow \text{v}_{128}$$

³⁴ <https://www.unicode.org/versions/latest/>

5.3.3 Heap Types

Heap types are encoded as either a single byte, or as a [type index](#) encoded as a positive signed integer.

<code>absheaptype</code>	<code>::=</code>	<code>0x69</code>	\Rightarrow	<code>exn</code>	
		<code> 0x6A</code>	\Rightarrow	<code>array</code>	
		<code> 0x6B</code>	\Rightarrow	<code>struct</code>	
		<code> 0x6C</code>	\Rightarrow	<code>i31</code>	
		<code> 0x6D</code>	\Rightarrow	<code>eq</code>	
		<code> 0x6E</code>	\Rightarrow	<code>any</code>	
		<code> 0x6F</code>	\Rightarrow	<code>extern</code>	
		<code> 0x70</code>	\Rightarrow	<code>func</code>	
		<code> 0x71</code>	\Rightarrow	<code>none</code>	
		<code> 0x72</code>	\Rightarrow	<code>noextern</code>	
		<code> 0x73</code>	\Rightarrow	<code>nofunc</code>	
		<code> 0x74</code>	\Rightarrow	<code>noexn</code>	
<code>heaptype</code>	<code>::=</code>	<code>ht:absheaptype</code>	\Rightarrow	<code>ht</code>	
		<code> x:s33</code>	\Rightarrow	<code>x</code>	if $x \geq 0$

Note

The heap type `bot` cannot occur in a module.

5.3.4 Reference Types

Reference types are either encoded by a single byte followed by a [heap type](#), or, as a short form, directly as an abstract heap type.

<code>reftype</code>	<code>::=</code>	<code>0x63 ht:heaptype</code>	\Rightarrow	<code>ref null ht</code>
		<code> 0x64 ht:heaptype</code>	\Rightarrow	<code>ref ht</code>
		<code> ht:absheaptype</code>	\Rightarrow	<code>ref null ht</code>

5.3.5 Value Types

Value types are encoded with their respective encoding as a [number type](#), [vector type](#), or [reference type](#).

<code>valtype</code>	<code>::=</code>	<code>nt:numtype</code>	\Rightarrow	<code>nt</code>
		<code> vt:vectype</code>	\Rightarrow	<code>vt</code>
		<code> rt:reftype</code>	\Rightarrow	<code>rt</code>

Note

The value type `bot` cannot occur in a module.

Value types can occur in contexts where [type indices](#) are also allowed, such as in the case of [block types](#). Thus, the binary format for types corresponds to the [signed LEB128](#)³⁵ encoding of small negative sN values, so that they can coexist with (positive) type indices in the future.

5.3.6 Result Types

Result types are encoded by the respective [lists](#) of value types.

<code>resulttype</code>	<code>::=</code>	<code>t*:list(valtype)</code>	\Rightarrow	<code>t*</code>
-------------------------	------------------	-------------------------------	---------------	-----------------

³⁵ https://en.wikipedia.org/wiki/LEB128#Signed_LEB128

5.3.7 Composite Types

Composite types are encoded by a distinct byte followed by a type encoding of the respective form.

<code>mut</code>	::=	<code>0x00</code>	⇒	ϵ
		<code>0x01</code>	⇒	<code>mut</code>
<code>comptype</code>	::=	<code>0x5E</code> <code>ft:fieldtype</code>	⇒	<code>array ft</code>
		<code>0x5F</code> <code>ft*:list(fieldtype)</code>	⇒	<code>struct ft*</code>
		<code>0x60</code> <code>t₁*:resulttype</code> <code>t₂*:resulttype</code>	⇒	<code>func t₁* → t₂*</code>
<code>fieldtype</code>	::=	<code>zt:storagetype</code> <code>mut?:mut</code>	⇒	<code>mut? zt</code>
<code>storagetype</code>	::=	<code>t:valtype</code>	⇒	<code>t</code>
		<code>pt:packtype</code>	⇒	<code>pt</code>
<code>packtype</code>	::=	<code>0x77</code>	⇒	<code>i16</code>
		<code>0x78</code>	⇒	<code>i8</code>

5.3.8 Recursive Types

Recursive types are encoded by the byte 0x4E followed by a list of sub types. Additional shorthands are recognized for unary recursions and sub types without super types.

<code>rectype</code>	::=	<code>0x4E</code> <code>st*:list(subtype)</code>	⇒	<code>rec st*</code>
		<code>st:subtype</code>	⇒	<code>rec st</code>
<code>subtype</code>	::=	<code>0x4F</code> <code>x*:list(typeidx)</code> <code>ct:comptype</code>	⇒	<code>sub final x* ct</code>
		<code>0x50</code> <code>x*:list(typeidx)</code> <code>ct:comptype</code>	⇒	<code>sub x* ct</code>
		<code>ct:comptype</code>	⇒	<code>sub final ϵ ct</code>

5.3.9 Limits

Limits are encoded with a preceding flag indicating whether a maximum is present, and a flag for the address type.

<code>limits_N</code>	::=	<code>0x00</code> <code>n:u64</code>	⇒	$(i32, [n .. 2^N - 1])$
		<code>0x01</code> <code>n:u64</code> <code>m:u64</code>	⇒	$(i32, [n .. m])$
		<code>0x04</code> <code>n:u64</code>	⇒	$(i64, [n .. 2^N - 1])$
		<code>0x05</code> <code>n:u64</code> <code>m:u64</code>	⇒	$(i64, [n .. m])$

5.3.10 Tag Types

Tag types are encoded by a type index denoting a function type.

<code>tagtype</code>	::=	<code>0x00</code> <code>x:typeidx</code>	⇒	<code>x</code>
----------------------	-----	--	---	----------------

Note

In future versions of WebAssembly, the preceding zero byte may encode additional attributes.

5.3.11 Global Types

Global types are encoded by their value type and a flag for their mutability.

<code>globaltype</code>	::=	<code>t:valtype</code> <code>mut?:mut</code>	⇒	<code>mut? t</code>
-------------------------	-----	--	---	---------------------

5.3.12 Memory Types

Memory types are encoded with their [limits](#).

$$\text{memtype} ::= (at, lim):limits_{|at|/(64\text{Ki})} \Rightarrow at\ lim\ page$$

5.3.13 Table Types

Table types are encoded with their [limits](#) and the encoding of their element [reference type](#).

$$\text{tabletype} ::= rt:reftype\ (at, lim):limits_{|at|} \Rightarrow at\ lim\ rt$$

5.3.14 External Types

External types are encoded by a distinguishing byte followed by an encoding of the respective form of type.

$\text{externtype} ::=$	0x00 $x:\text{typeid}$	\Rightarrow	$\text{func } x$
	0x01 $tt:\text{tabletype}$	\Rightarrow	$\text{table } tt$
	0x02 $mt:\text{memtype}$	\Rightarrow	$\text{mem } mt$
	0x03 $gt:\text{globaltype}$	\Rightarrow	$\text{global } gt$
	0x04 $jt:\text{tagtype}$	\Rightarrow	$\text{tag } jt$

5.4 Instructions

Instructions are encoded by *opcodes*. Each opcode is represented by a single byte, and is followed by the instruction's immediate arguments, where present. The only exception are [structured control instructions](#), which consist of several opcodes bracketing their nested instruction sequences.

Note

The byte codes chosen to encode instructions are historical and do not follow a consistent pattern. In this section, instructions are hence not presented in opcode order, but instead grouped consistently with other sections in this document. An instruction index ordered by opcode can be found in the [Appendix](#).

Gaps in the byte code ranges are reserved for future extensions.

5.4.1 Parametric Instructions

Parametric instructions are represented by single byte codes, possibly followed by a type annotation.

$\text{instr} ::=$	0x00	\Rightarrow	unreachable
	0x01	\Rightarrow	nop
	0x1A	\Rightarrow	drop
	0x1B	\Rightarrow	select
	0x1C $t^*:\text{list}(\text{valtype})$	\Rightarrow	$\text{select } t^*$
	...		

5.4.2 Control Instructions

Control instructions have varying encodings. For structured instructions, the instruction sequences forming nested blocks are delimited with explicit opcodes for end and else.

Block types are encoded in special compressed form, by either the byte 0x40 indicating the empty type, as a single value type, or as a type index encoded as a positive signed integer.

<code>blocktype</code>	<code>::=</code>	<code>0x40</code>	\Rightarrow	ϵ	
		<code> t:valtype</code>	\Rightarrow	t	
		<code> i:s33</code>	\Rightarrow	i	if $i \geq 0$
<code>instr</code>	<code>::=</code>	<code>...</code>			
		<code> 0x02 bt:blocktype (in:instr)* 0x0B</code>	\Rightarrow	<code>block bt in*</code>	
		<code> 0x03 bt:blocktype (in:instr)* 0x0B</code>	\Rightarrow	<code>loop bt in*</code>	
		<code> 0x04 bt:blocktype (in:instr)* 0x0B</code>	\Rightarrow	<code>if bt in* else ϵ</code>	
		<code> 0x04 bt:blocktype (in₁:instr)*</code>	\Rightarrow	<code>if bt in₁* else in₂*</code>	
		<code> 0x05 (in₂:instr)* 0x0B</code>			
		<code> 0x08 x:tagidx</code>	\Rightarrow	<code>throw x</code>	
		<code> 0x0A</code>	\Rightarrow	<code>throw_ref</code>	
		<code> 0x0C l:labelidx</code>	\Rightarrow	<code>br l</code>	
		<code> 0x0D l:labelidx</code>	\Rightarrow	<code>br_if l</code>	
		<code> 0x0E l*:list(labelidx) l_n:labelidx</code>	\Rightarrow	<code>br_table l* l_n</code>	
		<code> 0x0F</code>	\Rightarrow	<code>return</code>	
		<code> 0x10 x:funcidx</code>	\Rightarrow	<code>call x</code>	
		<code> 0x11 y:typeidx x:tableidx</code>	\Rightarrow	<code>call_indirect x y</code>	
		<code> 0x12 x:funcidx</code>	\Rightarrow	<code>return_call x</code>	
		<code> 0x13 y:typeidx x:tableidx</code>	\Rightarrow	<code>return_call_indirect x y</code>	
		<code> 0x1F bt:blocktype c*:list(catch) (in:instr)* 0x0B</code>	\Rightarrow	<code>try_table bt c* in*</code>	
		<code> ...</code>			
<code>catch</code>	<code>::=</code>	<code>0x00 x:tagidx l:labelidx</code>	\Rightarrow	<code>catch x l</code>	
		<code> 0x01 x:tagidx l:labelidx</code>	\Rightarrow	<code>catch_ref x l</code>	
		<code> 0x02 l:labelidx</code>	\Rightarrow	<code>catch_all l</code>	
		<code> 0x03 l:labelidx</code>	\Rightarrow	<code>catch_all_ref l</code>	

Note

The else opcode 0x05 in the encoding of an if instruction can be omitted if the following instruction sequence is empty.

Unlike any other occurrence, the type index in a block type is encoded as a positive signed integer, so that its signed LEB128 bit pattern cannot collide with the encoding of value types or the special code 0x40, which correspond to the LEB128 encoding of negative integers. To avoid any loss in the range of allowed indices, it is treated as a 33 bit signed integer.

5.4.3 Variable Instructions

Variable instructions are represented by byte codes followed by the encoding of the respective index.

<code>instr</code>	<code>::=</code>	<code>...</code>		
		<code> 0x20 x:localidx</code>	\Rightarrow	<code>local.get x</code>
		<code> 0x21 x:localidx</code>	\Rightarrow	<code>local.set x</code>
		<code> 0x22 x:localidx</code>	\Rightarrow	<code>local.tee x</code>
		<code> 0x23 x:globalidx</code>	\Rightarrow	<code>global.get x</code>
		<code> 0x24 x:globalidx</code>	\Rightarrow	<code>global.set x</code>
		<code> ...</code>		

5.4.4 Table Instructions

Table instructions are represented either by a single byte or a one byte prefix followed by a variable-length **unsigned integer**.

```

instr ::= ...
      | 0x25 x:tableidx           ⇒ table.get x
      | 0x26 x:tableidx           ⇒ table.set x
      | 0xFC 12:u32 y:elemidx x:tableidx ⇒ table.init x y
      | 0xFC 13:u32 x:elemidx       ⇒ elem.drop x
      | 0xFC 14:u32 x1:tableidx x2:tableidx ⇒ table.copy x1 x2
      | 0xFC 15:u32 x:tableidx       ⇒ table.grow x
      | 0xFC 16:u32 x:tableidx       ⇒ table.size x
      | 0xFC 17:u32 x:tableidx       ⇒ table.fill x
      | ...

```

5.4.5 Memory Instructions

Each variant of **memory instruction** is encoded with a different byte code. Loads and stores are followed by the encoding of their *memarg* immediate, which includes the **memory index** if bit 6 of the flags field containing alignment is set; the memory index defaults to 0 otherwise.

```

memarg ::= n:u32 m:u32           ⇒ (0, {align n, offset m})    if  $n < 2^6$ 
      | n:u32 x:memidx m:u32     ⇒ (x, {align (n - 2^6), offset m}) if  $2^6 \leq n < 2^7$ 

instr ::= ...
      | 0x28 (x, ao):memarg       ⇒ i32.load x ao
      | 0x29 (x, ao):memarg       ⇒ i64.load x ao
      | 0x2A (x, ao):memarg       ⇒ f32.load x ao
      | 0x2B (x, ao):memarg       ⇒ f64.load x ao
      | 0x2C (x, ao):memarg       ⇒ i32.load8_s x ao
      | 0x2D (x, ao):memarg       ⇒ i32.load8_u x ao
      | 0x2E (x, ao):memarg       ⇒ i32.load16_s x ao
      | 0x2F (x, ao):memarg       ⇒ i32.load16_u x ao
      | 0x30 (x, ao):memarg       ⇒ i64.load8_s x ao
      | 0x31 (x, ao):memarg       ⇒ i64.load8_u x ao
      | 0x32 (x, ao):memarg       ⇒ i64.load16_s x ao
      | 0x33 (x, ao):memarg       ⇒ i64.load16_u x ao
      | 0x34 (x, ao):memarg       ⇒ i64.load32_s x ao
      | 0x35 (x, ao):memarg       ⇒ i64.load32_u x ao
      | 0x36 (x, ao):memarg       ⇒ i32.store x ao
      | 0x37 (x, ao):memarg       ⇒ i64.store x ao
      | 0x38 (x, ao):memarg       ⇒ f32.store x ao
      | 0x39 (x, ao):memarg       ⇒ f64.store x ao
      | 0x3A (x, ao):memarg       ⇒ i32.store8 x ao
      | 0x3B (x, ao):memarg       ⇒ i32.store16 x ao
      | 0x3C (x, ao):memarg       ⇒ i64.store8 x ao
      | 0x3D (x, ao):memarg       ⇒ i64.store16 x ao
      | 0x3E (x, ao):memarg       ⇒ i64.store32 x ao
      | 0x3F x:memidx             ⇒ memory.size x
      | 0x40 x:memidx             ⇒ memory.grow x
      | 0xFC 8:u32 y:dataidx x:memidx ⇒ memory.init x y
      | 0xFC 9:u32 x:dataidx       ⇒ data.drop x
      | 0xFC 10:u32 x1:memidx x2:memidx ⇒ memory.copy x1 x2
      | 0xFC 11:u32 x:memidx       ⇒ memory.fill x
      | ...

```

5.4.6 Reference Instructions

Generic [reference instructions](#) are represented by single byte codes, others use prefixes and type operands.

<code>instr ::=</code>	<code>...</code>	
	<code>0xD0 <i>ht</i>:heaptypes</code>	\Rightarrow <code>ref.null <i>ht</i></code>
	<code>0xD1</code>	\Rightarrow <code>ref.is_null</code>
	<code>0xD2 <i>x</i>:funcidx</code>	\Rightarrow <code>ref.func <i>x</i></code>
	<code>0xD3</code>	\Rightarrow <code>ref.eq</code>
	<code>0xD4</code>	\Rightarrow <code>ref.as_non_null</code>
	<code>0xD5 <i>l</i>:labelidx</code>	\Rightarrow <code>br_on_null <i>l</i></code>
	<code>0xD6 <i>l</i>:labelidx</code>	\Rightarrow <code>br_on_non_null <i>l</i></code>
	<code>0xFB 0:u32 <i>x</i>:typeidx</code>	\Rightarrow <code>struct.new <i>x</i></code>
	<code>0xFB 1:u32 <i>x</i>:typeidx</code>	\Rightarrow <code>struct.new_default <i>x</i></code>
	<code>0xFB 2:u32 <i>x</i>:typeidx <i>i</i>:u32</code>	\Rightarrow <code>struct.get <i>x</i> <i>i</i></code>
	<code>0xFB 3:u32 <i>x</i>:typeidx <i>i</i>:u32</code>	\Rightarrow <code>struct.get_s <i>x</i> <i>i</i></code>
	<code>0xFB 4:u32 <i>x</i>:typeidx <i>i</i>:u32</code>	\Rightarrow <code>struct.get_u <i>x</i> <i>i</i></code>
	<code>0xFB 5:u32 <i>x</i>:typeidx <i>i</i>:u32</code>	\Rightarrow <code>struct.set <i>x</i> <i>i</i></code>
	<code>0xFB 6:u32 <i>x</i>:typeidx</code>	\Rightarrow <code>array.new <i>x</i></code>
	<code>0xFB 7:u32 <i>x</i>:typeidx</code>	\Rightarrow <code>array.new_default <i>x</i></code>
	<code>0xFB 8:u32 <i>x</i>:typeidx <i>n</i>:u32</code>	\Rightarrow <code>array.new_fixed <i>x</i> <i>n</i></code>
	<code>0xFB 9:u32 <i>x</i>:typeidx <i>y</i>:dataidx</code>	\Rightarrow <code>array.new_data <i>x</i> <i>y</i></code>
	<code>0xFB 10:u32 <i>x</i>:typeidx <i>y</i>:elemidx</code>	\Rightarrow <code>array.new_elem <i>x</i> <i>y</i></code>
	<code>0xFB 11:u32 <i>x</i>:typeidx</code>	\Rightarrow <code>array.get <i>x</i></code>
	<code>0xFB 12:u32 <i>x</i>:typeidx</code>	\Rightarrow <code>array.get_s <i>x</i></code>
	<code>0xFB 13:u32 <i>x</i>:typeidx</code>	\Rightarrow <code>array.get_u <i>x</i></code>
	<code>0xFB 14:u32 <i>x</i>:typeidx</code>	\Rightarrow <code>array.set <i>x</i></code>
	<code>0xFB 15:u32</code>	\Rightarrow <code>array.len</code>
	<code>0xFB 16:u32 <i>x</i>:typeidx</code>	\Rightarrow <code>array.fill <i>x</i></code>
	<code>0xFB 17:u32 <i>x</i>₁:typeidx <i>x</i>₂:typeidx</code>	\Rightarrow <code>array.copy <i>x</i>₁ <i>x</i>₂</code>
	<code>0xFB 18:u32 <i>x</i>:typeidx <i>y</i>:dataidx</code>	\Rightarrow <code>array.init_data <i>x</i> <i>y</i></code>
	<code>0xFB 19:u32 <i>x</i>:typeidx <i>y</i>:elemidx</code>	\Rightarrow <code>array.init_elem <i>x</i> <i>y</i></code>
	<code>0xFB 20:u32 <i>ht</i>:heaptypes</code>	\Rightarrow <code>ref.test (ref <i>ht</i>)</code>
	<code>0xFB 21:u32 <i>ht</i>:heaptypes</code>	\Rightarrow <code>ref.test (ref null <i>ht</i>)</code>
	<code>0xFB 22:u32 <i>ht</i>:heaptypes</code>	\Rightarrow <code>ref.cast (ref <i>ht</i>)</code>
	<code>0xFB 23:u32 <i>ht</i>:heaptypes</code>	\Rightarrow <code>ref.cast (ref null <i>ht</i>)</code>
	<code>0xFB 24:u32 (<i>null</i>₁[?], <i>null</i>₂[?]):castop</code>	\Rightarrow <code>br_on_cast <i>l</i> (ref null₁[?] <i>ht</i>₁) (ref null₂[?] <i>ht</i>₂)</code>
	<code><i>l</i>:labelidx <i>ht</i>₁:heaptypes <i>ht</i>₂:heaptypes</code>	
	<code>0xFB 25:u32 (<i>null</i>₁[?], <i>null</i>₂[?]):castop</code>	\Rightarrow <code>br_on_cast_fail <i>l</i> (ref null₁[?] <i>ht</i>₁) (ref null₂[?] <i>ht</i>₂)</code>
	<code><i>l</i>:labelidx <i>ht</i>₁:heaptypes <i>ht</i>₂:heaptypes</code>	
	<code>0xFB 26:u32</code>	\Rightarrow <code>any.convert_extern</code>
	<code>0xFB 27:u32</code>	\Rightarrow <code>extern.convert_any</code>
	<code>0xFB 28:u32</code>	\Rightarrow <code>ref.i31</code>
	<code>0xFB 29:u32</code>	\Rightarrow <code>i31.get_s</code>
	<code>0xFB 30:u32</code>	\Rightarrow <code>i31.get_u</code>
	<code>...</code>	
<code>castop ::=</code>	<code>0x00</code>	\Rightarrow <code>(ϵ, ϵ)</code>
	<code>0x01</code>	\Rightarrow <code>(null, ϵ)</code>
	<code>0x02</code>	\Rightarrow <code>(ϵ, null)</code>
	<code>0x03</code>	\Rightarrow <code>(null, null)</code>

5.4.7 Numeric Instructions

All variants of [numeric instructions](#) are represented by separate byte codes.

The const instructions are followed by the respective literal.

```

instr ::= ...
      | 0x41 n:u32 ⇒ i32.const n
      | 0x42 n:u64 ⇒ i64.const n
      | 0x43 p:f32 ⇒ f32.const p
      | 0x44 p:f64 ⇒ f64.const p
      | ...

```

All other numeric instructions are plain opcodes without any immediates.

```

instr ::= ...
      | 0x45 ⇒ i32.eqz
      | 0x46 ⇒ i32.eq
      | 0x47 ⇒ i32.ne
      | 0x48 ⇒ i32.lt
      | 0x49 ⇒ i32.lt
      | 0x4A ⇒ i32.gt
      | 0x4B ⇒ i32.gt
      | 0x4C ⇒ i32.le
      | 0x4D ⇒ i32.le
      | 0x4E ⇒ i32.ge
      | 0x4F ⇒ i32.ge
      | 0x50 ⇒ i64.eqz
      | 0x51 ⇒ i64.eq
      | 0x52 ⇒ i64.ne
      | 0x53 ⇒ i64.lt
      | 0x54 ⇒ i64.lt
      | 0x55 ⇒ i64.gt
      | 0x56 ⇒ i64.gt
      | 0x57 ⇒ i64.le
      | 0x58 ⇒ i64.le
      | 0x59 ⇒ i64.ge
      | 0x5A ⇒ i64.ge
      | ...

```

```

instr ::= ...
      | 0x5B ⇒ f32.eq
      | 0x5C ⇒ f32.ne
      | 0x5D ⇒ f32.lt
      | 0x5E ⇒ f32.gt
      | 0x5F ⇒ f32.le
      | 0x60 ⇒ f32.ge
      | 0x61 ⇒ f64.eq
      | 0x62 ⇒ f64.ne
      | 0x63 ⇒ f64.lt
      | 0x64 ⇒ f64.gt
      | 0x65 ⇒ f64.le
      | 0x66 ⇒ f64.ge
      | ...

```

```
instr ::= ...  
      | 0x67 ⇒ i32.clz  
      | 0x68 ⇒ i32.ctz  
      | 0x69 ⇒ i32.popcnt  
      | 0x6A ⇒ i32.add  
      | 0x6B ⇒ i32.sub  
      | 0x6C ⇒ i32.mul  
      | 0x6D ⇒ i32.div  
      | 0x6E ⇒ i32.div  
      | 0x6F ⇒ i32.rem  
      | 0x70 ⇒ i32.rem  
      | 0x71 ⇒ i32.and  
      | 0x72 ⇒ i32.or  
      | 0x73 ⇒ i32.xor  
      | 0x74 ⇒ i32.shl  
      | 0x75 ⇒ i32.shr  
      | 0x76 ⇒ i32.shr  
      | 0x77 ⇒ i32.rotl  
      | 0x78 ⇒ i32.rotr  
      | 0x79 ⇒ i64.clz  
      | 0x7A ⇒ i64.ctz  
      | 0x7B ⇒ i64.popcnt  
      | 0x7C ⇒ i64.add  
      | 0x7D ⇒ i64.sub  
      | 0x7E ⇒ i64.mul  
      | 0x7F ⇒ i64.div  
      | 0x80 ⇒ i64.div  
      | 0x81 ⇒ i64.rem  
      | 0x82 ⇒ i64.rem  
      | 0x83 ⇒ i64.and  
      | 0x84 ⇒ i64.or  
      | 0x85 ⇒ i64.xor  
      | 0x86 ⇒ i64.shl  
      | 0x87 ⇒ i64.shr  
      | 0x88 ⇒ i64.shr  
      | 0x89 ⇒ i64.rotl  
      | 0x8A ⇒ i64.rotr  
      | ...
```

```

instr ::= ...
| 0x8B ⇒ f32.abs
| 0x8C ⇒ f32.neg
| 0x8D ⇒ f32.ceil
| 0x8E ⇒ f32.floor
| 0x8F ⇒ f32.trunc
| 0x90 ⇒ f32.nearest
| 0x91 ⇒ f32.sqrt
| 0x92 ⇒ f32.add
| 0x93 ⇒ f32.sub
| 0x94 ⇒ f32.mul
| 0x95 ⇒ f32.div
| 0x96 ⇒ f32.min
| 0x97 ⇒ f32.max
| 0x98 ⇒ f32.copysign
| 0x99 ⇒ f64.abs
| 0x9A ⇒ f64.neg
| 0x9B ⇒ f64.ceil
| 0x9C ⇒ f64.floor
| 0x9D ⇒ f64.trunc
| 0x9E ⇒ f64.nearest
| 0x9F ⇒ f64.sqrt
| 0xA0 ⇒ f64.add
| 0xA1 ⇒ f64.sub
| 0xA2 ⇒ f64.mul
| 0xA3 ⇒ f64.div
| 0xA4 ⇒ f64.min
| 0xA5 ⇒ f64.max
| 0xA6 ⇒ f64.copysign
| ...

```

```

instr ::= ...
| 0xA7 ⇒ i32.wrap_i64
| 0xA8 ⇒ i32.trunc_f32
| 0xA9 ⇒ i32.trunc_f32
| 0xAA ⇒ i32.trunc_f64
| 0xAB ⇒ i32.trunc_f64
| 0xAC ⇒ i64.extend_i32
| 0xAD ⇒ i64.extend_i32
| 0xAE ⇒ i64.trunc_f32
| 0xAF ⇒ i64.trunc_f32
| 0xB0 ⇒ i64.trunc_f64
| 0xB1 ⇒ i64.trunc_f64
| 0xB2 ⇒ f32.convert_i32
| 0xB3 ⇒ f32.convert_i32
| 0xB4 ⇒ f32.convert_i64
| 0xB5 ⇒ f32.convert_i64
| 0xB6 ⇒ f32.demote_f64
| 0xB7 ⇒ f64.convert_i32
| 0xB8 ⇒ f64.convert_i32
| 0xB9 ⇒ f64.convert_i64
| 0xBA ⇒ f64.convert_i64
| 0xBB ⇒ f32.promote_f64
| 0xBC ⇒ i32.reinterpret_f32
| 0xBD ⇒ i64.reinterpret_f64
| 0xBE ⇒ f32.reinterpret_i32
| 0xBF ⇒ f64.reinterpret_i64
| ...

```

```

instr ::= ...
      | 0xC0 ⇒ i32.extend
      | 0xC1 ⇒ i32.extend
      | 0xC2 ⇒ i64.extend
      | 0xC3 ⇒ i64.extend
      | 0xC4 ⇒ i64.extend
      | ...

```

The saturating truncation instructions all have a one byte prefix, whereas the actual opcode is encoded by a variable-length [unsigned integer](#).

```

instr ::= ...
      | 0xFC 0:u32 ⇒ i32.trunc_sat_f32
      | 0xFC 1:u32 ⇒ i32.trunc_sat_f32
      | 0xFC 2:u32 ⇒ i32.trunc_sat_f64
      | 0xFC 3:u32 ⇒ i32.trunc_sat_f64
      | 0xFC 4:u32 ⇒ i64.trunc_sat_f32
      | 0xFC 5:u32 ⇒ i64.trunc_sat_f32
      | 0xFC 6:u32 ⇒ i64.trunc_sat_f64
      | 0xFC 7:u32 ⇒ i64.trunc_sat_f64
      | ...

```

5.4.8 Vector Instructions

All variants of [vector instructions](#) are represented by separate byte codes. They all have a one byte prefix, whereas the actual opcode is encoded by a variable-length [unsigned integer](#).

Vector loads and stores are followed by the encoding of their [memarg](#) immediate.

```

laneidx ::= l:byte ⇒ l
instr ::= ...
      | 0xFD 0:u32 (x, ao):memarg ⇒ v128.load x ao
      | 0xFD 1:u32 (x, ao):memarg ⇒ v128.load8x8_s x ao
      | 0xFD 2:u32 (x, ao):memarg ⇒ v128.load8x8_u x ao
      | 0xFD 3:u32 (x, ao):memarg ⇒ v128.load16x4_s x ao
      | 0xFD 4:u32 (x, ao):memarg ⇒ v128.load16x4_u x ao
      | 0xFD 5:u32 (x, ao):memarg ⇒ v128.load32x2_s x ao
      | 0xFD 6:u32 (x, ao):memarg ⇒ v128.load32x2_u x ao

```

The const instruction for vectors is followed by 16 immediate bytes, which are converted into an [u128](#) in

littleendian byte order:

```
instr ::= ...
      | 0xFD 12:u32 (b:byte)16 ⇒ v128.const bytesi128-1((b)16)
      | ...
```

The shuffle instruction is also followed by the encoding of 16 *laneidx* immediates.

```
instr ::= ...
      | 0xFD 13:u32 (l:laneidx)16 ⇒ i8x16.shuffle l16
      | 0xFD 14:u32                ⇒ i8x16.swizzle
      | 0xFD 256:u32                ⇒ i8x16.relaxed_swizzle
      | ...
```

Lane instructions are followed by the encoding of a *laneidx* immediate.

```
instr ::= ...
      | 0xFD 21:u32 l:laneidx ⇒ i8x16.extract_lane_s l
      | 0xFD 22:u32 l:laneidx ⇒ i8x16.extract_lane_u l
      | 0xFD 23:u32 l:laneidx ⇒ i8x16.replace_lane l
      | 0xFD 24:u32 l:laneidx ⇒ i16x8.extract_lane_s l
      | 0xFD 25:u32 l:laneidx ⇒ i16x8.extract_lane_u l
      | 0xFD 26:u32 l:laneidx ⇒ i16x8.replace_lane l
      | 0xFD 27:u32 l:laneidx ⇒ i32x4.extract_lane l
      | 0xFD 28:u32 l:laneidx ⇒ i32x4.replace_lane l
      | 0xFD 29:u32 l:laneidx ⇒ i64x2.extract_lane l
      | 0xFD 30:u32 l:laneidx ⇒ i64x2.replace_lane l
      | 0xFD 31:u32 l:laneidx ⇒ f32x4.extract_lane l
      | 0xFD 32:u32 l:laneidx ⇒ f32x4.replace_lane l
      | 0xFD 33:u32 l:laneidx ⇒ f64x2.extract_lane l
      | 0xFD 34:u32 l:laneidx ⇒ f64x2.replace_lane l
      | ...
```

All other vector instructions are plain opcodes without any immediates.

```

      | 0xFD 270:u32 ⇒ f32x4.relaxed_max
      | 0xFD 271:u32 ⇒ f64x2.relaxed_min
      | 0xFD 272:u32 ⇒ f64x2.relaxed_max
      | 0xFD 273:u32 ⇒ i16x8.relaxed_q15mulr_s
      | 0xFD 274:u32 ⇒ i16x8.relaxed_dot_i8x16_i7x16_s
      | 0xFD 275:u32 ⇒ i16x8.relaxed_dot_i8x16_i7x16_add_s

```

5.4.9 Expressions

Expressions are encoded by their instruction sequence terminated with an explicit 0x0B opcode for end.

$$\text{expr} ::= (\text{in}:\text{instr})^* 0x0B \Rightarrow \text{in}^*$$

5.5 Modules

The binary encoding of modules is organized into *sections*. Most sections correspond to one component of a *module* record, except that *function definitions* are split into two sections, separating their type declarations in the *function section* from their bodies in the *code section*.

Note

This separation enables *parallel* and *streaming* compilation of the functions in a module.

5.5.1 Indices

All basic [indices](#) are encoded with their respective value.

```

typeidx ::= x:u32 ⇒ x
funcidx ::= x:u32 ⇒ x
tableidx ::= x:u32 ⇒ x
memidx ::= x:u32 ⇒ x
globalidx ::= x:u32 ⇒ x
tagidx ::= x:u32 ⇒ x
elemidx ::= x:u32 ⇒ x
dataidx ::= x:u32 ⇒ x
localidx ::= x:u32 ⇒ x
labelidx ::= l:u32 ⇒ l

```

External [indices](#) are encoded by a distinguishing byte followed by an encoding of their respective value.

```

externidx ::= 0x00 x:funcidx ⇒ func x
           | 0x01 x:tableidx ⇒ table x
           | 0x02 x:memidx ⇒ memory x
           | 0x03 x:globalidx ⇒ global x
           | 0x04 x:tagidx ⇒ tag x

```

5.5.2 Sections

Each section consists of

- a one-byte section *id*,
- the *u32* *length* of the contents, in bytes,
- the actual *contents*, whose structure is dependent on the section *id*.

Every section is optional; an omitted section is equivalent to the section being present with empty contents.

The following parameterized grammar rule defines the generic structure of a section with *id* *N* and contents described by the grammar *X*.

$$\begin{array}{lcl}
 \text{section}_N(X) & ::= & N:\text{byte} \text{ } len:\text{u32} \text{ } en^*:X \Rightarrow en^* \text{ if } len = ||X|| \\
 & | & \epsilon \Rightarrow \epsilon
 \end{array}$$

For most sections, the contents *X* encodes a [list](#). In these cases, the empty result ϵ is interpreted as the empty list.

Note

Other than for unknown [custom](#) sections, the *size* is not required for decoding, but can be used to skip sections when navigating through a binary. The module is malformed if the size does not match the length of the binary contents *X*.

The following section *ids* are used:

Id	Section
0	custom section
1	type section
2	import section
3	function section
4	table section
5	memory section
6	global section
7	export section
8	start section
9	element section
10	code section
11	data section
12	data count section
13	tag section

Note

Section ids do not always correspond to the [order of sections](#) in the encoding of a module.

5.5.3 Custom Section

Custom sections have the id 0. They are intended to be used for debugging information or third-party extensions, and are ignored by the WebAssembly semantics. Their contents consist of a [name](#) further identifying the custom section, followed by an uninterpreted sequence of bytes for custom use.

```
customsec ::= section0(custom)
custom    ::= name byte*
```

Note

If an implementation interprets the data of a custom section, then errors in that data, or the placement of the section, must not invalidate the module.

5.5.4 Type Section

The *type section* has the id 1. It decodes into the list of [recursive types](#) of a [module](#).

```
typesec ::= ty*:section1(list(type)) ⇒ ty*
type    ::= qt:rectype                ⇒ type qt
```

5.5.5 Import Section

The *import section* has the id 2. It decodes into the list of [imports](#) of a [module](#).

```
importsec ::= im*:section2(list(import)) ⇒ im*
import    ::= nm1:name nm2:name xt:externtype ⇒ import nm1 nm2 xt
```

5.5.6 Function Section

The *function section* has the id 3. It decodes into a list of [type indices](#) that classify the [functions](#) defined by a [module](#). The bodies of the respective functions are encoded separately in the [code section](#).

$$\text{funcsec} ::= x^*:\text{section}_3(\text{list}(\text{typeid}x)) \Rightarrow x^*$$

5.5.7 Table Section

The *table section* has the id 4. It decodes into the list of [tables](#) defined by a [module](#).

$$\begin{aligned} \text{tablesec} &::= \text{tab}^*:\text{section}_4(\text{list}(\text{table})) &\Rightarrow \text{tab}^* \\ \text{table} &::= \text{tt}:\text{tabletype} &\Rightarrow \text{table } \text{tt} \text{ (ref.null ht) if } \text{tt} = \text{at lim (ref null? ht)} \\ &| 0x40 \text{ } 0x00 \text{ } \text{tt}:\text{tabletype} \text{ } e:\text{expr} &\Rightarrow \text{table } \text{tt} \text{ } e \end{aligned}$$

Note

The encoding of a table type cannot start with byte 0x40, hence decoding is unambiguous. The zero byte following it is reserved for future extensions.

5.5.8 Memory Section

The *memory section* has the id 5. It decodes into the list of [memories](#) defined by a [module](#).

$$\begin{aligned} \text{memsec} &::= \text{mem}^*:\text{section}_5(\text{list}(\text{mem})) &\Rightarrow \text{mem}^* \\ \text{mem} &::= \text{mt}:\text{memtype} &\Rightarrow \text{memory } \text{mt} \end{aligned}$$

5.5.9 Global Section

The *global section* has the id 6. It decodes into the list of [globals](#) defined by a [module](#).

$$\begin{aligned} \text{globalsec} &::= \text{glob}^*:\text{section}_6(\text{list}(\text{global})) &\Rightarrow \text{glob}^* \\ \text{global} &::= \text{gt}:\text{globaltype} \text{ } e:\text{expr} &\Rightarrow \text{global } \text{gt} \text{ } e \end{aligned}$$

5.5.10 Export Section

The *export section* has the id 7. It decodes into the list of [exports](#) of a [module](#).

$$\begin{aligned} \text{exportsec} &::= \text{ex}^*:\text{section}_7(\text{list}(\text{export})) &\Rightarrow \text{ex}^* \\ \text{export} &::= \text{nm}:\text{name} \text{ } \text{xx}:\text{externidx} &\Rightarrow \text{export } \text{nm} \text{ } \text{xx} \end{aligned}$$

5.5.11 Start Section

The *start section* has the id 8. It decodes into the optional [start function](#) of a [module](#).

$$\begin{aligned} \text{startsec} &::= \text{start}^?:\text{section}_8(\text{start}) &\Rightarrow \text{start}^? \\ \text{start} &::= x:\text{funcidx} &\Rightarrow (\text{start } x) \end{aligned}$$

5.5.12 Element Section

The *element section* has the id 9. It decodes into the list of *element segments* defined by a *module*.

```

elemsec ::= elem*:section9(list(elem))           ⇒ elem*
elemkind ::= 0x00                                ⇒ ref null func
elem ::= 0:u32 eo:expr y*:list(funcidx)          ⇒
        elem (ref func) (ref.func y)* (active 0 eo)
        | 1:u32 rt:elemkind y*:list(funcidx)      ⇒
        elem rt (ref.func y)* passive
        | 2:u32 x:tableidx e:expr rt:elemkind y*:list(funcidx) ⇒
        elem rt (ref.func y)* (active x e)
        | 3:u32 rt:elemkind y*:list(funcidx)      ⇒
        elem rt (ref.func y)* declare
        | 4:u32 eo:expr e*:list(expr)            ⇒
        elem (ref null func) e* (active 0 eo)
        | 5:u32 rt:reftype e*:list(expr)          ⇒
        elem rt e* passive
        | 6:u32 x:tableidx eo:expr e*:list(expr) ⇒
        elem (ref null func) e* (active x eo)
        | 7:u32 rt:reftype e*:list(expr)          ⇒
        elem rt e* declare

```

Note

The initial integer can be interpreted as a bitfield. Bit 0 distinguishes a passive or declarative segment from an active segment, bit 1 indicates the presence of an explicit table index for an active segment and otherwise distinguishes passive from declarative segments, bit 2 indicates the use of element type and element *expressions* instead of element kind and element indices.

Additional element kinds may be added in future versions of WebAssembly.

5.5.13 Code Section

The *code section* has the id 10. It decodes into the list of *code entries* that are pairs of lists of *locals* and *expressions*. They represent the body of the *functions* defined by a *module*. The types of the respective functions are encoded separately in the *function section*.

The encoding of each code entry consists of

- the *u32 length* of the function code in bytes,
- the actual *function code*, which in turn consists of
 - the declaration of *locals*,
 - the function *body* as an *expression*.

Local declarations are compressed into a list whose entries consist of

- a *u32 count*,
- a *value type*,

denoting *count* locals of the same value type.

```

codesec ::= code*:section10(list(code)) ⇒ code*
code    ::= len:u32 code:func           ⇒ code    if len = ||func||
func    ::= loc*:list(locals) e:expr    ⇒ (⊕ loc**, e) if |⊕ loc**| < 232
locals  ::= n:u32 t:valtype             ⇒ (local t)n

```

Here, *code* ranges over pairs (*local**, *expr*). Any code for which the length of the resulting sequence is out of bounds of the maximum size of a *list* is malformed.

Note

Like with [sections](#), the code *size* is not needed for decoding, but can be used to skip functions when navigating through a binary. The module is malformed if a size does not match the length of the respective function code.

5.5.14 Data Section

The *data section* has the id 11. It decodes into the list of [data segments](#) defined by a [module](#).

<code>datasec</code>	<code>::=</code>	<code>data*:section₁₁(list(data))</code>	\Rightarrow	<code>data*</code>
<code>data</code>	<code>::=</code>	<code>0:u32 e:expr b*:list(byte)</code>	\Rightarrow	<code>data b* (active 0 e)</code>
		<code> 1:u32 b*:list(byte)</code>	\Rightarrow	<code>data b* passive</code>
		<code> 2:u32 x:memidx e:expr b*:list(byte)</code>	\Rightarrow	<code>data b* (active x e)</code>

Note

The initial integer can be interpreted as a bitfield. Bit 0 indicates a passive segment, bit 1 indicates the presence of an explicit memory index for an active segment.

5.5.15 Data Count Section

The *data count section* has the id 12. It decodes into an optional *u32* count that represents the number of [data segments](#) in the [data section](#). If this count does not match the length of the data segment list, the module is malformed.

<code>datacntsec</code>	<code>::=</code>	<code>n?:section₁₂(datacnt)</code>	\Rightarrow	<code>n?</code>
<code>datacnt</code>	<code>::=</code>	<code>n:u32</code>	\Rightarrow	<code>n</code>

Note

The data count section is used to simplify single-pass validation. Since the data section occurs after the code section, the `memory.init` and `data.drop` instructions would not be able to check whether the data segment index is valid until the data section is read. The data count section occurs before the code section, so a single-pass validator can use this count instead of deferring validation.

5.5.16 Tag Section

The *tag section* has the id 13. It decodes into the list of [tags](#) defined by a [module](#).

<code>tagsec</code>	<code>::=</code>	<code>tag*:section₁₃(list(tag))</code>	\Rightarrow	<code>tag*</code>
<code>tag</code>	<code>::=</code>	<code>jt:tagtype</code>	\Rightarrow	<code>tag jt</code>

5.5.17 Modules

The encoding of a [module](#) starts with a preamble containing a 4-byte magic number (the string ‘\0asm’) and a version field. The current version of the WebAssembly binary format is 1.

The preamble is followed by a sequence of [sections](#). [Custom sections](#) may be inserted at any place in this sequence, while other sections must occur at most once and in the prescribed order. All sections can be empty.

The lengths of lists produced by the (possibly empty) [function](#) and [code](#) section must match up.

Similarly, the optional data count must match the length of the [data segment](#) list. Furthermore, it must be present if any [data index](#) occurs in the code section.

```

magic ::= 0x00 0x61 0x73 0x6D
version ::= 0x01 0x00 0x00 0x00
module ::= magic version ⇒
  customsec* type*:typesec
  customsec* import*:importsec
  customsec* typeid*:funcsec
  customsec* table*:tablesec
  customsec* mem*:memsec
  customsec* tag*:tagsec
  customsec* global*:globalsec
  customsec* export*:exportsec
  customsec* start?:startsec
  customsec* elem*:elemsec
  customsec* n?:datacntsec
  customsec* (local*, expr)*:codesec
  customsec* data*:datasec
  customsec*
    module type* import* tag* global* mem* table* func* data* elem* start? export*
    if (n = |data*|)?
    ∧ (n? ≠ ε ∨ dataidx(func*) = ε)
    ∧ (func = func typeid local* expr)*

```

Note

The version of the WebAssembly binary format may increase in the future if backward-incompatible changes have to be made to the format. However, such changes are expected to occur very infrequently, if ever. The binary format is intended to be extensible, such that future features can be added without incrementing its version.

6.1 Conventions

The textual format for WebAssembly **modules** is a rendering of their **abstract syntax** into **S-expressions**³⁶.

Like the **binary format**, the text format is defined by an *attribute grammar*. A text string is a well-formed description of a module if and only if it is generated by the grammar. Each production of this grammar has at most one synthesized attribute: the abstract syntax that the respective character sequence expresses. Thus, the attribute grammar implicitly defines a *parsing* function. Some productions also take a **context** as an inherited attribute that records bound **identifiers**.

Except for a few exceptions, the core of the text grammar closely mirrors the grammar of the abstract syntax. However, it also defines a number of *abbreviations* that are “syntactic sugar” over the core syntax.

The recommended extension for files containing WebAssembly modules in text format is “.wat”. Files with this extension are assumed to be encoded in UTF-8, as per **Unicode**³⁷ (Section 2.5).

6.1.1 Grammar

The following conventions are adopted in defining grammar rules of the text format. They mirror the conventions used for **abstract syntax** and for the **binary format**. In order to distinguish symbols of the textual syntax from symbols of the abstract syntax, typewriter font is adopted for the former.

- Terminal symbols are either literal strings of characters enclosed in quotes or expressed as **Unicode**³⁸ scalar values: ‘module’, U+0A. (All characters written literally are unambiguously drawn from the 7-bit **ASCII**³⁹ subset of Unicode.)
- Nonterminal symbols are written in typewriter font: `valtype`, `instr`.
- T^n is a sequence of $n \geq 0$ iterations of T .
- T^* is a possibly empty sequence of iterations of T . (This is a shorthand for T^n used where n is not relevant.)
- T^+ is a possibly empty sequence of iterations of T . (This is a shorthand for T^n used where n is not relevant.)
- $T^?$ is an optional occurrence of T . (This is a shorthand for T^n where $n \leq 1$.)

³⁶ <https://en.wikipedia.org/wiki/S-expression>

³⁷ <https://www.unicode.org/versions/latest/>

³⁸ <https://www.unicode.org/versions/latest/>

³⁹ <https://webstore.ansi.org/RecordDetail.aspx?sku=INCITS+4-1986%5bR2012%5d>

- $x:T$ denotes the same language as the nonterminal T , but also binds the variable x to the attribute synthesized for T . A pattern may also be used instead of a variable, e.g., $7:T$.
- Productions are written $\text{sym} ::= T_1 \Rightarrow A_1 \mid \dots \mid T_n \Rightarrow A_n$, where each A_i is the attribute that is synthesized for sym in the given case, usually from attribute variables bound in T_i .
- Large productions may be split into multiple definitions, indicated by ending the first one with explicit ellipses, $\text{sym} ::= B_1 \mid \dots$, and starting continuations with ellipses, $\text{sym} ::= \dots \mid B_2$.
- Some productions are augmented by side conditions in parentheses, which restrict the applicability of the production. They provide a shorthand for a combinatorial expansion of the production into many separate cases.
- If the same meta variable or non-terminal symbol appears multiple times in a production (in the syntax or in an attribute), then all those occurrences must have the same instantiation.
- A distinction is made between *lexical* and *syntactic* productions. For the latter, arbitrary **white space** is allowed in any place where the grammar contains spaces. The productions defining **lexical syntax** and the syntax of **values** are considered lexical, all others are syntactic.

Note

For example, the **textual grammar** for **number types** is given as follows:

$$\begin{array}{lcl} \text{numtype} & ::= & \text{'i32'} \Rightarrow \text{i32} \\ & & \mid \text{'i64'} \Rightarrow \text{i64} \\ & & \mid \text{'f32'} \Rightarrow \text{f32} \\ & & \mid \text{'f64'} \Rightarrow \text{f64} \end{array}$$

The **textual grammar** for **limits** is defined as follows:

$$\begin{array}{lcl} \text{limits}_N & ::= & n:\text{u64} \Rightarrow [n \dots 2^N] \\ & & \mid n:\text{u64} \ m:\text{u64} \Rightarrow [n \dots m] \end{array}$$

The variables n and m name the attributes of the respective **u64** nonterminals, which in this case are the actual **unsigned integers** those parse into. The attribute of the complete production then is the abstract syntax for the limit, expressed in terms of the former values.

The variable N is a *parameter* to the grammar symbol that can be instantiated differently at each use site. In this example, it controls the value range of the limits.

6.1.2 Abbreviations

In addition to the core grammar, which corresponds directly to the **abstract syntax**, the textual syntax also defines a number of *abbreviations* that can be used for convenience and readability.

Abbreviations are defined by *rewrite rules* specifying their expansion into the core syntax:

$$\text{sym} ::= \text{abbreviated syntax} \equiv \text{expanded syntax}$$

These expansions are assumed to be applied, recursively and in order of appearance, before applying the core grammar rules to construct the abstract syntax.

6.1.3 Contexts

The text format allows the use of symbolic **identifiers** in place of **indices**. To resolve these identifiers into concrete indices, some grammar productions are indexed by an *identifier context* I as a synthesized attribute that records the declared identifiers in each **index space**. In addition, the context records the types defined in the module, so that **parameter** indices can be computed for **functions**.

It is convenient to define identifier contexts as *records* I with abstract syntax as follows:

$$I ::= \{ \text{types } (name^?)^* \\ \text{tags } (name^?)^* \\ \text{globals } (name^?)^* \\ \text{mems } (name^?)^* \\ \text{tables } (name^?)^* \\ \text{funcs } (name^?)^* \\ \text{datas } (name^?)^* \\ \text{elems } (name^?)^* \\ \text{locals } (name^?)^* \\ \text{labels } (name^?)^* \\ \text{fields } ((name^?)^*)^* \\ \text{typedefs } (subtype^?)^* \}$$

For each index space, such a context contains the list of *names* assigned to the defined indices, which were denoted by the corresponding *identifiers*. Unnamed indices are associated with empty (ϵ) entries in these lists. Fields have *dependent* name spaces, and hence a separate list of field identifiers per type.

An identifier context is *well-formed* if no index space contains duplicate identifiers. For fields, names need only be unique within a single type.

Conventions

To avoid unnecessary clutter, empty components are omitted when writing out identifier contexts. For example, the record $\{\}$ is shorthand for an *identifier context* whose components are all empty.

6.1.4 Lists

Lists are written as plain sequences, but with a restriction on the length of these sequence.

$$\text{list}(X) ::= (el:X)^* \Rightarrow el^* \text{ if } |el^*| < 2^{32}$$

6.2 Lexical Format

6.2.1 Characters

The text format assigns meaning to *source text*, which consists of a sequence of *characters*. Characters are assumed to be represented as valid *Unicode*⁴⁰ (Section 2.4) *scalar values*.

```
source ::= char*
char   ::= U+00 | ... | U+D7FF | U+E000 | ... | U+10FFFF
```

Note

While source text may contain any Unicode character in *comments* or *string* literals, the rest of the grammar is formed exclusively from the characters supported by the 7-bit *ASCII*⁴¹ subset of Unicode.

6.2.2 Tokens

The character stream in the source text is divided, from left to right, into a sequence of *tokens*, as defined by the following grammar.

```
token ::= keyword | u | s | f | string | id | '(' | ')' | reserved
keyword ::= ('a' | ... | 'z') idchar*
reserved ::= (idchar | string | ';' | ':' | '[' | ']' | '{' | '}')+
```

⁴⁰ <https://www.unicode.org/versions/latest/>

⁴¹ <https://webstore.ansi.org/RecordDetail.aspx?sku=INCITS+4-1986%5bR2012%5d>

Tokens are formed from the input character stream according to the *longest match* rule. That is, the next token always consists of the longest possible sequence of characters that is recognized by the above lexical grammar. Tokens can be separated by [white space](#), but except for strings, they cannot themselves contain whitespace.

Keyword tokens always start with a lower-case letter. The set of keywords is defined implicitly: only those tokens are defined to be keywords that occur as a [terminal symbol](#) in literal form, such as ‘keyword’, in a [syntactic](#) production of this chapter.

Any token that does not fall into any of the other categories is considered *reserved*, and cannot occur in source text.

Note

The effect of defining the set of reserved tokens is that all tokens must be separated by either parentheses, [white space](#), or [comments](#). For example, ‘0\$x’ is a single reserved token, as is ‘“a”b”’. Consequently, they are not recognized as two separate tokens ‘0’ and ‘\$x’, or ‘“a”’ and ‘“b”’, respectively, but instead disallowed. This property of tokenization is not affected by the fact that the definition of reserved tokens overlaps with other token classes.

6.2.3 White Space

White space is any sequence of literal space characters, formatting characters, [comments](#), or [annotations](#). The allowed formatting characters correspond to a subset of the [ASCII](#)⁴² *format effectors*, namely, *horizontal tabulation* (U+09), *line feed* (U+0A), and *carriage return* (U+0D).

```
space ::= (‘ | format | comment | annot)*
format ::= newline | U+09
newline ::= U+0A | U+0D | U+0D U+0A
```

The only relevance of white space is to separate [tokens](#). It is otherwise ignored.

6.2.4 Comments

A *comment* can either be a *line comment*, started with a double semicolon ‘;;’ and extending to the end of the line, or a *block comment*, enclosed in delimiters ‘(;’ ... ‘;)’ . Block comments can be nested.

```
comment ::= linecomment | blockcomment
linecomment ::= ‘;;’ linechar* (newline | eof)
linechar ::= c:char if c ≠ U+0A ∧ c ≠ U+0D
blockcomment ::= ‘(;’ blockchar* ‘;)’
blockchar ::= c:char if c ≠ ‘;’ ∧ c ≠ ‘(’
| ‘;’+ c:char if c ≠ ‘;’ ∧ c ≠ ‘)’
| ‘(’+ c:char if c ≠ ‘(’ ∧ c ≠ ‘(’
| blockcomment
```

Here, the pseudo token `eof` indicates the end of the input. The *look-ahead* restrictions on the productions for `blockchar` disambiguate the grammar such that only well-bracketed uses of block comment delimiters are allowed.

Note

Any formatting and control characters are allowed inside comments.

6.2.5 Annotations

An *annotation* is a bracketed token sequence headed by an *annotation id* of the form ‘@id’ or ‘@“...”’ . No [space](#) is allowed between the opening parenthesis and this id. Annotations are intended to be used for third-party extensions;

⁴² <https://webstore.ansi.org/RecordDetail.aspx?sku=INCITS+4-1986%5bR2012%5d>

they can appear anywhere in a program but are ignored by the WebAssembly semantics itself, which treats them as [white space](#).

Annotations can contain other parenthesized token sequences (including nested annotations), as long as they are well-nested. [String literals](#) and [comments](#) occurring in an annotation must also be properly nested and closed.

```
annot ::= '(@' annotid (space | token)* ')'
annotid ::= idchar+ | name
```

Note

The annotation id is meant to be an identifier categorising the extension, and plays a role similar to the name of a [custom section](#). By convention, annotations corresponding to a custom section should use the custom section's name as an id.

Implementations are expected to ignore annotations with ids that they do not recognize. On the other hand, they may impose restrictions on annotations that they do recognize, e.g., requiring a specific structure by superimposing a more concrete grammar. It is up to an implementation how it deals with errors in such annotations.

6.3 Values

The grammar productions in this section define *lexical syntax*, hence no [white space](#) is allowed.

6.3.1 Integers

All [integers](#) can be written in either decimal or hexadecimal notation. In both cases, digits can optionally be separated by underscores.

```
sign ::= ε ⇒ +1 | '+' ⇒ +1 | '-' ⇒ -1
digit ::= '0' ⇒ 0 | ... | '9' ⇒ 9
hexdigit ::= d:digit ⇒ d
           | 'A' ⇒ 10 | ... | 'F' ⇒ 15
           | 'a' ⇒ 10 | ... | 'f' ⇒ 15
num ::= d:digit ⇒ d
      | n:num '_'? d:digit ⇒ 10n + d
hexnum ::= h:hexdigit ⇒ h
        | n:hexnum '_'? h:hexdigit ⇒ 16n + h
```

The allowed syntax for integer literals depends on size and signedness. Moreover, their value must lie within the range of the respective type.

```
uN ::= n:num ⇒ n      if n < 2N
    | '0x' n:hexnum ⇒ n  if n < 2N
sN ::= s:sign n:uN ⇒ s · n  if -2N-1 ≤ s · n < 2N-1
```

[Uninterpreted integers](#) can be written as either signed or unsigned, and are normalized to unsigned in the abstract syntax.

```
iN ::= n:uN ⇒ n
     | i:sN ⇒ signedN-1(i)
```

6.3.2 Floating-Point

Floating-point values can be represented in either decimal or hexadecimal notation.

<code>frac</code>	<code>::= d:digit</code>	$\Rightarrow d/10$
	<code> d:digit ‘_’? p:frac</code>	$\Rightarrow (d + p/10)/10$
<code>hexfrac</code>	<code>::= h:hexdigit</code>	$\Rightarrow h/16$
	<code> h:hexdigit ‘_’? p:hexfrac</code>	$\Rightarrow (h + p/16)/16$
<code>mant</code>	<code>::= p:num ‘.’?</code>	$\Rightarrow p$
	<code> p:num ‘.’ q:frac</code>	$\Rightarrow p + q$
<code>hexmant</code>	<code>::= p:hexnum ‘.’?</code>	$\Rightarrow p$
	<code> p:hexnum ‘.’ q:hexfrac</code>	$\Rightarrow p + q$
<code>float</code>	<code>::= p:mant (‘E’ ‘e’) s:sign e:num</code>	$\Rightarrow p \cdot 10^{s \cdot e}$
<code>hexfloat</code>	<code>::= ‘0x’ p:hexmant (‘P’ ‘p’) s:sign e:num</code>	$\Rightarrow p \cdot 2^{s \cdot e}$

The value of a literal must not lie outside the representable range of the corresponding IEEE 754⁴³ type (that is, a numeric value must not overflow to $\pm\infty$), but it may be **rounded** to the nearest representable value.

Note

Rounding can be prevented by using hexadecimal notation with no more significant bits than supported by the required type.

Floating-point values may also be written as constants for *infinity* or *canonical NaN* (*not a number*). Furthermore, arbitrary NaN values may be expressed by providing an explicit payload value.

<code>fN</code>	<code>::= (+1):sign q:fNmag</code>	$\Rightarrow +q$
	<code> (-1):sign q:fNmag</code>	$\Rightarrow -q$
<code>fNmag</code>	<code>::= q:float</code>	$\Rightarrow \text{float}_N(q)$ if $\text{float}_N(q) \neq \infty$
	<code> q:hexfloat</code>	$\Rightarrow \text{float}_N(q)$ if $\text{float}_N(q) \neq \infty$
	<code> ‘inf’</code>	$\Rightarrow \infty$
	<code> ‘nan’</code>	$\Rightarrow \text{nan}(\text{canon}_N)$
	<code> ‘nan : 0x’ n:hexnum</code>	$\Rightarrow \text{nan}(n)$ if $1 \leq n < 2^{\text{signif}(N)}$

6.3.3 Strings

Strings denote sequences of bytes that can represent both textual and binary data. They are enclosed in quotation marks and may contain any character other than ASCII⁴⁴ control characters, quotation marks (‘’), or backslash (‘\’), except when expressed with an *escape sequence*.

<code>string</code>	<code>::= ‘’ (b*:stringelem)* ‘’</code>	$\Rightarrow \bigoplus b^{**}$ if $ \bigoplus b^{**} < 2^{32}$
<code>stringelem</code>	<code>::= c:stringchar</code>	$\Rightarrow \text{utf8}(c)$
	<code> ‘\’ h₁:hexdigit h₂:hexdigit</code>	$\Rightarrow 16 h_1 + h_2$

Each character in a string literal represents the byte sequence corresponding to its UTF-8 Unicode⁴⁵ (Section 2.5) encoding, except for hexadecimal escape sequences ‘\hh’, which represent raw bytes of the respective value.

<code>stringchar</code>	<code>::= c:char</code>	$\Rightarrow c$ if $c \geq \text{U}+20 \wedge c \neq \text{U}+7\text{F} \wedge c \neq \text{’’} \wedge c \neq \text{’\’}$
	<code> ‘\t’</code>	$\Rightarrow \text{U}+09$
	<code> ‘\n’</code>	$\Rightarrow \text{U}+0\text{A}$
	<code> ‘\r’</code>	$\Rightarrow \text{U}+0\text{D}$
	<code> ‘\’’</code>	$\Rightarrow \text{U}+22$
	<code> ‘\,’</code>	$\Rightarrow \text{U}+27$
	<code> ‘\’</code>	$\Rightarrow \text{U}+5\text{C}$
	<code> ‘\u{’ n:hexnum ‘}’</code>	$\Rightarrow n$ if $n < 0\text{x}\text{D}800 \vee 0\text{x}\text{E}800 \leq n < 0\text{x}110000$

⁴³ <https://ieeexplore.ieee.org/document/8766229>

⁴⁴ <https://webstore.ansi.org/RecordDetail.aspx?sku=INCITS+4-1986%5bR2012%5d>

⁴⁵ <https://www.unicode.org/versions/latest/>

6.3.4 Names

Names are strings denoting a literal character sequence. A name string must form a valid UTF-8 encoding as defined by [Unicode](#)⁴⁶ (Section 2.5) and is interpreted as a string of Unicode scalar values.

$$\text{name} ::= b^*:\text{string} \Rightarrow c^* \text{ if } b^* = \text{utf8}(c^*)$$

Note

Presuming the source text is itself encoded correctly, strings that do not contain any uses of hexadecimal byte escapes are always valid names.

6.3.5 Identifiers

Indices can be given in both numeric and symbolic form. Symbolic *identifiers* that stand in lieu of indices start with ‘\$’, followed by either a sequence of printable [ASCII](#)⁴⁷ characters that does not contain a space, quotation mark, comma, semicolon, or bracket, or by a quoted **name**.

$$\begin{aligned} \text{id} &::= \text{‘\$’ } c^*:\text{idchar}^+ && \Rightarrow c^* \\ &| \text{‘\$’ } c^*:\text{name} && \Rightarrow c^* \text{ if } |c^*| > 0 \\ \text{idchar} &::= \text{‘0’} | \dots | \text{‘9’} \\ &| \text{‘A’} | \dots | \text{‘Z’} \\ &| \text{‘a’} | \dots | \text{‘z’} \\ &| \text{‘!’} | \text{‘\#’} | \text{‘$’} | \text{‘\%’} | \text{‘\&’} | \text{‘\’} | \text{‘*’} | \text{‘+’} | \text{‘-’} | \text{‘.’} | \text{‘/’} \\ &| \text{‘:’} | \text{‘<’} | \text{‘=’} | \text{‘>’} | \text{‘?’} | \text{‘@’} | \text{‘\’} | \text{‘^’} | \text{‘_’} | \text{‘~’} | \text{‘|’} | \text{‘~’} \end{aligned}$$

Note

The value of an identifier character is the Unicode codepoint denoting it.

Conventions

The expansion rules of some abbreviations require insertion of a *fresh* identifier. That may be any syntactically valid identifier that does not already occur in the given source text.

6.4 Types

6.4.1 Number Types

$$\begin{aligned} \text{numtype} &::= \text{‘i32’} \Rightarrow \text{i32} \\ &| \text{‘i64’} \Rightarrow \text{i64} \\ &| \text{‘f32’} \Rightarrow \text{f32} \\ &| \text{‘f64’} \Rightarrow \text{f64} \end{aligned}$$

6.4.2 Vector Types

$$\text{vectype} ::= \text{‘v128’} \Rightarrow \text{v128}$$

⁴⁶ <https://www.unicode.org/versions/latest/>

⁴⁷ <https://webstore.ansi.org/RecordDetail.aspx?sku=INCITS+4-1986%5bR2012%5d>

6.4.3 Heap Types

<code>absheaptypes</code>	<code>::=</code>	<code>'any'</code>	\Rightarrow	<code>any</code>
		<code>'eq'</code>	\Rightarrow	<code>eq</code>
		<code>'i31'</code>	\Rightarrow	<code>i31</code>
		<code>'struct'</code>	\Rightarrow	<code>struct</code>
		<code>'array'</code>	\Rightarrow	<code>array</code>
		<code>'none'</code>	\Rightarrow	<code>none</code>
		<code>'func'</code>	\Rightarrow	<code>func</code>
		<code>'nofunc'</code>	\Rightarrow	<code>nofunc</code>
		<code>'exn'</code>	\Rightarrow	<code>exn</code>
		<code>'noexn'</code>	\Rightarrow	<code>noexn</code>
		<code>'extern'</code>	\Rightarrow	<code>extern</code>
		<code>'noextern'</code>	\Rightarrow	<code>noextern</code>
<code>heaptypes_I</code>	<code>::=</code>	<code>ht:absheaptypes</code>	\Rightarrow	<code>ht</code>
		<code>x:typeidx_I</code>	\Rightarrow	<code>x</code>

6.4.4 Reference Types

<code>null</code>	<code>::=</code>	<code>'null'</code>	\Rightarrow	<code>null</code>
<code>reftypes_I</code>	<code>::=</code>	<code>(' 'ref' null?:null? ht:heaptypes_I '')</code>	\Rightarrow	<code>ref null? ht</code>
		<code>...</code>		

Abbreviations

There are shorthands for references to abstract heap types.

<code>reftypes_I</code>	<code>::=</code>	<code>...</code>
		<code>'anyref' ≡ (' 'ref' 'null' 'any' '')</code>
		<code>'eqref' ≡ (' 'ref' 'null' 'eq' '')</code>
		<code>'i31ref' ≡ (' 'ref' 'null' 'i31' '')</code>
		<code>'structref' ≡ (' 'ref' 'null' 'struct' '')</code>
		<code>'arrayref' ≡ (' 'ref' 'null' 'array' '')</code>
		<code>'nullref' ≡ (' 'ref' 'null' 'none' '')</code>
		<code>'funcref' ≡ (' 'ref' 'null' 'func' '')</code>
		<code>'nullfuncref' ≡ (' 'ref' 'null' 'nofunc' '')</code>
		<code>'exnref' ≡ (' 'ref' 'null' 'exn' '')</code>
		<code>'nullexnref' ≡ (' 'ref' 'null' 'noexn' '')</code>
		<code>'externref' ≡ (' 'ref' 'null' 'extern' '')</code>
		<code>'nullexternref' ≡ (' 'ref' 'null' 'noextern' '')</code>

6.4.5 Value Types

<code>valtypes_I</code>	<code>::=</code>	<code>nt:numtype</code>	\Rightarrow	<code>nt</code>
		<code>vt:vectype</code>	\Rightarrow	<code>vt</code>
		<code>rt:reftypes_I</code>	\Rightarrow	<code>rt</code>

6.4.6 Composite Types

Composite types are parsed into their respective abstract representation, paired with the local [identifier context](#) generated by their bound field or parameter identifiers:

comptype_I	$::=$	$((' \text{'struct'} (ft, id^?)^*: \text{list}(\text{field}_I) \text{'})$	\Rightarrow	$(\text{struct } ft^*, \{\text{fields } (id^?)^*\})$
		$ $		
		$((' \text{'array'} ft: \text{fieldtype}_I \text{'})$	\Rightarrow	$(\text{array } ft, \{\})$
		$ $		
		$((' \text{'func'} (t_1, id^?)^*: \text{list}(\text{param}_I) t_2: \text{list}(\text{result}_I) \text{'})$	\Rightarrow	$(\text{func } t_1^* \rightarrow t_2^*, \{\})$
field_I	$::=$	$((' \text{'field'} id^?: id^? ft: \text{fieldtype}_I \text{'})$	\Rightarrow	$(ft, id^?)$
		$ $		
		\dots		
param_I	$::=$	$((' \text{'param'} id^?: id^? t: \text{valtype}_I \text{'})$	\Rightarrow	$(t, id^?)$
		$ $		
		\dots		
result_I	$::=$	$((' \text{'result'} t: \text{valtype}_I \text{'})$	\Rightarrow	t
		$ $		
		\dots		
fieldtype_I	$::=$	$zt: \text{storagetype}_I$	\Rightarrow	zt
		$ $		
		$((' \text{'mut'} zt: \text{storagetype}_I \text{'})$	\Rightarrow	$\text{mut } zt$
storagetype_I	$::=$	$t: \text{valtype}_I$	\Rightarrow	t
		$ $		
		$pt: \text{packtype}$	\Rightarrow	pt
packtype	$::=$	'i8'	\Rightarrow	i8
		$ $		
		'i16'	\Rightarrow	i16

Note

The optional identifier names for parameters in a function type only have documentation purpose. They cannot be referenced from anywhere.

Abbreviations

Multiple anonymous structure fields or parameters or multiple results may be combined into a single declaration:

field_I	$::=$	\dots	$ $	$((' \text{'field'} \text{fieldtype}_I^* \text{'})$	\equiv	$((' \text{'field'} \text{fieldtype}_I \text{'})^*$
param_I	$::=$	\dots	$ $	$((' \text{'param'} \text{valtype}_I^* \text{'})$	\equiv	$((' \text{'param'} \text{valtype}_I \text{'})^*$
result_I	$::=$	\dots	$ $	$((' \text{'result'} \text{valtype}_I^* \text{'})$	\equiv	$((' \text{'param'} \text{valtype}_I \text{'})^*$

6.4.7 Recursive Types

Recursive types are parsed into their respective abstract representation, paired with the [identifier context](#) generated by their bound identifiers:

final	$::=$	'final'	\Rightarrow	final
subtype_I	$::=$	$((' \text{'sub'} fin^?: \text{final}^? x^*: \text{list}(\text{typeid}_I) (ct, I'): \text{comptype}_I \text{'})$	\Rightarrow	$(\text{sub } fin^? x^* ct, I')$
		$ $		
		\dots		
typedef_I	$::=$	$((' \text{'type'} id^?: id^? (st, I'): \text{subtype}_I \text{'})$	\Rightarrow	$(st, I' \oplus \{\text{types } (id^?)^*\})$
rectype_I	$::=$	$((' \text{'rec'} (st, I')^*: \text{list}(\text{typedef}_I) \text{'})$	\Rightarrow	$(\text{rec } st^*, \text{concat}_{idctx}(I'^*))$
		$ $		
		\dots		

Abbreviations

Final sub types with no super-types can omit the 'sub' keyword and its arguments:

subtype_I	$::=$	\dots	$ $	comptype_I	\equiv	$((' \text{'sub'} \text{'final'} \text{comptype}_I \text{'})$
--------------------	-------	---------	-----	---------------------	----------	---

Similarly, singular recursive types can omit the 'rec' keyword:

rectype_I	$::=$	\dots	$ $	typedef_I	\equiv	$((' \text{'rec'} \text{typedef}_I \text{'})$
--------------------	-------	---------	-----	--------------------	----------	---

6.4.8 Address Types

$$\begin{aligned} \text{addrtype} &::= \text{'i32'} \Rightarrow \text{i32} \\ &\quad | \text{'i64'} \Rightarrow \text{i64} \\ &\quad | \dots \end{aligned}$$

Abbreviations

The address type can be omitted, in which case it defaults `i32`:

$$\text{addrtype} ::= \dots \mid \epsilon \equiv \text{'i32'}$$

6.4.9 Limits

$$\begin{aligned} \text{limits}_N &::= n:\text{u64} \Rightarrow [n \dots 2^N] \\ &\quad | n:\text{u64 } m:\text{u64} \Rightarrow [n \dots m] \end{aligned}$$

6.4.10 Tag Types

$$\text{tagtype}_I ::= (x, I'):\text{typeuse}_I \Rightarrow x$$

6.4.11 Global Types

$$\begin{aligned} \text{globaltype}_I &::= t:\text{valtype}_I \Rightarrow t \\ &\quad | \text{'(' 'mut' } t:\text{valtype}_I \text{' ')} \Rightarrow \text{mut } t \end{aligned}$$

6.4.12 Memory Types

$$\text{memtype}_I ::= at:\text{addrtype } lim:\text{limits}_{|at|-16} \Rightarrow at \text{ } lim \text{ page}$$

6.4.13 Table Types

$$\text{tabletype}_I ::= at:\text{addrtype } lim:\text{limits}_{|at|} rt:\text{reftype}_I \Rightarrow at \text{ } lim \text{ } rt$$

6.4.14 External Types

$$\begin{aligned} \text{externtype}_I &::= \text{'(' 'tag' } id^?:id^? \text{ } jt:\text{tagtype}_I \text{' ')} \Rightarrow (\text{tag } jt, \{\text{tags } (id^?)\}) \\ &\quad | \text{'(' 'global' } id^?:id^? \text{ } gt:\text{globaltype}_I \text{' ')} \Rightarrow (\text{global } gt, \{\text{globals } (id^?)\}) \\ &\quad | \text{'(' 'memory' } id^?:id^? \text{ } mt:\text{memtype}_I \text{' ')} \Rightarrow (\text{mem } mt, \{\text{mems } (id^?)\}) \\ &\quad | \text{'(' 'table' } id^?:id^? \text{ } tt:\text{tabletype}_I \text{' ')} \Rightarrow (\text{table } tt, \{\text{tables } (id^?)\}) \\ &\quad | \text{'(' 'func' } id^?:id^? \text{ } (x, I'):\text{typeuse}_I \text{' ')} \Rightarrow (\text{func } x, \{\text{funcs } (id^?)\}) \end{aligned}$$

6.4.15 Type Uses

A *type use* is a reference to a [type definition](#). Where it is required to reference a [function type](#), it may optionally be augmented by explicit inlined [parameter](#) and [result](#) declarations. That allows binding symbolic [identifiers](#) to name the [local indices](#) of parameters. If inline declarations are given, then their types must match the referenced [function type](#).

$$\begin{aligned}
 \text{typeuse}_I &::= \text{'(' 'type' } x:\text{typeid}_I \text{' ')} && \Rightarrow (x, I') \\
 &\quad \text{if } I.\text{typedefs}[x] = \text{sub final (func } t_1^* \rightarrow t_2^*) \\
 &\quad \wedge I' = \{\text{locals } (\epsilon)^{|t_1^*|}\} \\
 &| \text{'(' 'type' } x:\text{typeid}_I \text{' ')} (t_1, id^?):\text{param}_I^* t_2^*:\text{result}_I^* && \Rightarrow (x, I') \\
 &\quad \text{if } I.\text{typedefs}[x] = \text{sub final (func } t_1^* \rightarrow t_2^*) \\
 &\quad \wedge I' = \{\text{locals } (id^?)^*\} \\
 &\quad \wedge \vdash I' : \text{ok} \\
 &| \dots
 \end{aligned}$$

Note

If inline declarations are given, their types must be *syntactically* equal to the types from the indexed definition; possible type [substitutions](#) from other definitions that might make them equal are not taken into account. This is to simplify syntactic pre-processing.

The synthesized attribute of a *typeuse* is a pair consisting of both the used [type index](#) and the local [identifier context](#) containing possible parameter identifiers.

Note

Both productions overlap for the case that the function type is `func $\epsilon \rightarrow \epsilon$` . However, in that case, they also produce the same results, so that the choice is immaterial.

The [well-formedness](#) condition on I' ensures that the parameters do not contain duplicate identifiers.

Abbreviations

A type use may also be replaced entirely by inline [parameter](#) and [result](#) declarations. In that case, a [type index](#) is automatically inserted:

$$\begin{aligned}
 \text{typeuse}_I &::= \dots | (t_1, id^?):\text{param}_I^* t_2^*:\text{result}_I^* \equiv \text{'(' 'type' } x:\text{typeid}_I \text{' ')} \text{param}_I^* \text{result}_I^* \\
 &\quad \text{if } I.\text{typedefs}[x] = \text{sub final (func } t_1^* \rightarrow t_2^*) \\
 &\quad \wedge (I.\text{typedefs}[i] \neq \text{sub final (func } t_1^* \rightarrow t_2^*))^{i < x}
 \end{aligned}$$

where x is the smallest existing [type index](#) whose [recursive type](#) definition parses into a singular, final [function type](#) with the same parameters and results. If no such index exists, then a new [recursive type](#) of the same form is inserted at the end of the module.

Abbreviations are expanded in the order they appear, such that previously inserted type definitions are reused by consecutive expansions.

6.5 Instructions

Instructions are syntactically distinguished into *plain* and *structured* instructions.

$$\begin{aligned}
 \text{instr}_I &::= \text{in:plaininstr}_I \Rightarrow \text{in} \\
 &| \text{in:blockinstr}_I \Rightarrow \text{in}
 \end{aligned}$$

In addition, as a syntactic abbreviation, instructions can be written as S-expressions in [folded](#) form, to group them visually.

6.5.1 Labels

Structured control instructions can be annotated with a symbolic label identifier. They are the only symbolic identifiers that can be bound locally in an instruction sequence. The following grammar handles the corresponding update to the identifier context by composing the context with an additional label entry.

$$\begin{array}{lcl} \text{label}_I & ::= & v:\text{id} \Rightarrow v, \{\text{labels } v\} \oplus I \quad (\text{if } v \notin I.\text{labels}) \\ & | & v:\text{id} \Rightarrow v, \{\text{labels } v\} \oplus (I \text{ with labels}[i] = \epsilon) \quad (\text{if } I.\text{labels}[i] = v) \\ & | & \epsilon \Rightarrow \epsilon, \{\text{labels } (\epsilon)\} \oplus I \end{array}$$

Note

The new label entry is inserted at the *beginning* of the label list in the identifier context. This effectively shifts all existing labels up by one, mirroring the fact that control instructions are indexed relatively not absolutely.

If a label with the same name already exists, then it is shadowed and the earlier label becomes inaccessible.

6.5.2 Parametric Instructions

$$\begin{array}{lcl} \text{plaininstr}_I & ::= & \dots \\ & | & \text{'drop'} \Rightarrow \text{drop} \\ & | & \text{'select'} ((t:\text{result}_I)^*)^? \Rightarrow \text{select } (t^*)^? \end{array}$$

6.5.3 Control Instructions

Structured control instructions can bind an optional symbolic label identifier. The same label identifier may optionally be repeated after the corresponding end or else keywords, to indicate the matching delimiters.

Their block type is given as a type use, analogous to the type of functions. However, the special case of a type use that is syntactically empty or consists of only a single result is not regarded as an abbreviation for an inline function type, but is parsed directly into an optional value type.

$$\begin{array}{lcl} \text{blocktype}_I & ::= & (t:\text{result}_I)^? \Rightarrow t^? \\ & | & x, I':\text{typeuse}_I \Rightarrow x \quad (\text{if } I' = \{\text{locals } (\epsilon)^*\}) \\ \text{blockinstr}_I & ::= & \text{'block'} (v^?, I'):\text{label}_I \text{ bt}:\text{blocktype}_I (in:\text{instr}_{I'})^* \text{'end'} v'^?:\text{id}^? \\ & \Rightarrow & \text{block } bt \text{ in}^* \quad (\text{if } v'^? = \epsilon \vee v'^? = v^?) \\ & | & \text{'loop'} (v^?, I'):\text{label}_I \text{ bt}:\text{blocktype}_I (in:\text{instr}_{I'})^* \text{'end'} v'^?:\text{id}^? \\ & \Rightarrow & \text{loop } bt \text{ in}^* \quad (\text{if } v'^? = \epsilon \vee v'^? = v^?) \\ & | & \text{'if'} (v^?, I'):\text{label}_I \text{ bt}:\text{blocktype}_I (in_1:\text{instr}_{I'})^* \text{'else'} v_1^?:\text{id}_1^? (in_2:\text{instr}_{I'})^* \text{'end'} v_2^?:\text{id}_2^? \\ & \Rightarrow & \text{if } bt \text{ in}_1^* \text{ else } in_2^* \quad (\text{if } v_1^? = \epsilon \vee v_1^? = v^?, v_2^? = \epsilon \vee v_2^? = v^?) \\ & | & \text{'try_table'} I':\text{label}_I \text{ bt}:\text{blocktype}_I (c:\text{catch}_I)^* (in:\text{instr}_{I'})^* \text{'end'} id^? \\ & \Rightarrow & \text{try_table } bt \text{ c}^* \text{ in}^* \quad (\text{if } id^? = \epsilon \vee id^? = \text{label}) \\ \text{catch}_I & ::= & \text{'(' 'catch' x:tagidx}_I \text{ l:labelidx}_I \text{')'} \Rightarrow \text{catch } x \text{ l} \\ & | & \text{'(' 'catch_ref' x:tagidx}_I \text{ l:labelidx}_I \text{')'} \Rightarrow \text{catch_ref } x \text{ l} \\ & | & \text{'(' 'catch_all' l:labelidx}_I \text{')'} \Rightarrow \text{catch_all } l \\ & | & \text{'(' 'catch_all_ref' l:labelidx}_I \text{')'} \Rightarrow \text{catch_all_ref } l \end{array}$$

Note

The side condition stating that the identifier context I' must only contain unnamed entries in the rule for typeuse block types enforces that no identifier can be bound in any param declaration for a block type.

All other control instruction are represented verbatim.

<code>plaininstr_I</code>	<code>::=</code>	<code>'unreachable'</code>	\Rightarrow	<code>unreachable</code>	
		<code>'nop'</code>	\Rightarrow	<code>nop</code>	
		<code>'br' l:labelidx_I</code>	\Rightarrow	<code>br l</code>	
		<code>'br_if' l:labelidx_I</code>	\Rightarrow	<code>br_if l</code>	
		<code>'br_table' l*:list(labelidx_I) l_N:labelidx_I</code>	\Rightarrow	<code>br_table l* l_N</code>	
		<code>'br_on_null' l:labelidx_I</code>	\Rightarrow	<code>br_on_null l</code>	
		<code>'br_on_non_null' l:labelidx_I</code>	\Rightarrow	<code>br_on_non_null l</code>	
		<code>'br_on_cast' l:labelidx_I t₁:reftype t₂:reftype</code>	\Rightarrow	<code>br_on_cast l t₁ t₂</code>	
		<code>'br_on_cast_fail' l:labelidx_I t₁:reftype t₂:reftype</code>	\Rightarrow	<code>br_on_cast_fail l t₁ t₂</code>	
		<code>'return'</code>	\Rightarrow	<code>return</code>	
		<code>'call' x:funcidx_I</code>	\Rightarrow	<code>call x</code>	
		<code>'call_ref' x:typeidx</code>	\Rightarrow	<code>call_ref x</code>	
		<code>'call_indirect' x:tableidx y, I':typeuse_I</code>	\Rightarrow	<code>call_indirect x y</code>	(if $I' = 0$)
		<code>'return_call' x:funcidx_I</code>	\Rightarrow	<code>return_call x</code>	
		<code>'return_call_ref' x:typeidx</code>	\Rightarrow	<code>return_call_ref x</code>	
		<code>'return_call_indirect' x:tableidx y, I':typeuse_I</code>	\Rightarrow	<code>return_call_indirect x y</code>	(if $I' = 0$)
		<code>'throw' x:tagidx_I</code>	\Rightarrow	<code>throw x</code>	
		<code>'throw_ref'</code>	\Rightarrow	<code>throw_ref</code>	
		<code>...</code>			

Note

The side condition stating that the [identifier context](#) I' must only contain unnamed entries in the rule for `call_indirect` enforces that no identifier can be bound in any [param](#) declaration appearing in the type annotation.

Abbreviations

The 'else' keyword of an 'if' instruction can be omitted if the following instruction sequence is empty.

`'if' label blocktypeI instr* 'end'` \equiv `'if' label blocktypeI instr* 'else' 'end'`

Also, for backwards compatibility, the table index to 'call_indirect' and 'return_call_indirect' can be omitted, defaulting to 0.

`'call_indirect' typeuse` \equiv `'call_indirect' 0 typeuse`
`'return_call_indirect' typeuse` \equiv `'return_call_indirect' 0 typeuse`

6.5.4 Variable Instructions

<code>plaininstr_I</code>	<code>::=</code>	<code>...</code>	
		<code>'local.get' x:localidx_I</code>	\Rightarrow <code>local.get x</code>
		<code>'local.set' x:localidx_I</code>	\Rightarrow <code>local.set x</code>
		<code>'local.tee' x:localidx_I</code>	\Rightarrow <code>local.tee x</code>
		<code>'global.get' x:globalidx_I</code>	\Rightarrow <code>global.get x</code>
		<code>'global.set' x:globalidx_I</code>	\Rightarrow <code>global.set x</code>

6.5.5 Table Instructions

<code>plaininstr_I</code>	<code>::=</code>	<code>...</code>	
		<code>'table.get' x:tableidx_I</code>	\Rightarrow <code>table.get x</code>
		<code>'table.set' x:tableidx_I</code>	\Rightarrow <code>table.set x</code>
		<code>'table.size' x:tableidx_I</code>	\Rightarrow <code>table.size x</code>
		<code>'table.grow' x:tableidx_I</code>	\Rightarrow <code>table.grow x</code>
		<code>'table.fill' x:tableidx_I</code>	\Rightarrow <code>table.fill x</code>
		<code>'table.copy' x:tableidx_I y:tableidx_I</code>	\Rightarrow <code>table.copy x y</code>
		<code>'table.init' x:tableidx_I y:elemidx_I</code>	\Rightarrow <code>table.init x y</code>
		<code>'elem.drop' x:elemidx_I</code>	\Rightarrow <code>elem.drop x</code>

Abbreviations

For backwards compatibility, all [table indices](#) may be omitted from table instructions, defaulting to 0.

<code>'table.get'</code>	\equiv	<code>'table.get' '0'</code>
<code>'table.set'</code>	\equiv	<code>'table.set' '0'</code>
<code>'table.size'</code>	\equiv	<code>'table.size' '0'</code>
<code>'table.grow'</code>	\equiv	<code>'table.grow' '0'</code>

<code>'table.copy'</code>	\equiv	<code>'table.copy' '0' '0'</code>
<code>'table.init' x:elemidx_I</code>	\equiv	<code>'table.init' '0' x:elemidx_I</code>

6.5.6 Memory Instructions

The offset and alignment immediates to memory instructions are optional. The offset defaults to 0, the alignment to the storage size of the respective memory access, which is its *natural alignment*. Lexically, an [offset](#) or [align](#)

phrase is considered a single **keyword token**, so no **white space** is allowed around the ‘=’.

<code>memarg_N</code>	<code>::= o:offset a:align_N</code>	\Rightarrow	<code>{align <i>n</i>, offset <i>o</i>}</code>	(i
<code>offset</code>	<code>::= ‘offset=’o:u64</code>	\Rightarrow	<code><i>o</i></code>	
	<code> ϵ</code>	\Rightarrow	<code>0</code>	
<code>align_N</code>	<code>::= ‘align=’a:u64</code>	\Rightarrow	<code><i>a</i></code>	
	<code> ϵ</code>	\Rightarrow	<code><i>N</i></code>	
<code>plaininstr_I</code>	<code>::= ...</code>			
	<code>‘i32.load’ x:memidx_I m:memarg₄</code>	\Rightarrow	<code>i32.load <i>x m</i></code>	
	<code>‘i64.load’ x:memidx_I m:memarg₈</code>	\Rightarrow	<code>i64.load <i>x m</i></code>	
	<code>‘f32.load’ x:memidx_I m:memarg₄</code>	\Rightarrow	<code>f32.load <i>x m</i></code>

	<code>‘data.drop’ x:dataidx_I</code>	\Rightarrow	<code>data.drop <i>x</i></code>	

Abbreviations

As an abbreviation, the memory index can be omitted in all memory instructions, defaulting to 0.

<code>numtype.load memarg</code>	<code>≡ numtype.load '0' memarg</code>
<code>vectype.load memarg</code>	<code>≡ vectype.load '0' memarg</code>
<code>numtype.load N'_sx memarg</code>	<code>≡ numtype.load N'_sx '0' memarg</code>
<code>vectype.load NxM'_sx memarg</code>	<code>≡ vectype.load NxM'_sx '0' memarg</code>
<code>vectype.load N'_splat memarg</code>	<code>≡ vectype.load N'_splat '0' memarg</code>
<code>vectype.load N'_zero memarg</code>	<code>≡ vectype.load N'_zero '0' memarg</code>
<code>vectype.load N'_lane memarg u8</code>	<code>≡ vectype.load N'_lane '0' memarg u8</code>
<code>numtype.store memarg</code>	<code>≡ numtype.store '0' memarg</code>
<code>vectype.store memarg</code>	<code>≡ vectype.store '0' memarg</code>
<code>numtype.store N memarg</code>	<code>≡ numtype.store N '0' memarg</code>
<code>vectype.store N'_lane memarg u8</code>	<code>≡ vectype.store N'_lane '0' memarg u8</code>
<code>'memory.size'</code>	<code>≡ 'memory.size' '0'</code>
<code>'memory.grow'</code>	<code>≡ 'memory.grow' '0'</code>
<code>'memory.fill'</code>	<code>≡ 'memory.fill' '0'</code>
<code>'memory.copy'</code>	<code>≡ 'memory.copy' '0' '0'</code>
<code>'memory.init' x:elemidx_I</code>	<code>≡ 'memory.init' '0' x:elemidx_I</code>

6.5.7 Reference Instructions

<code>plaininstr_I ::= ...</code>	
<code>'ref.null' t:heaptypex_I</code>	<code>⇒ ref.null t</code>

6.5.9 Vector Instructions

Vector constant instructions have a mandatory [shape](#) descriptor, which determines how the following values are parsed.

'v128.const' 'i8x16' (n:i8) ¹⁶	⇒	v128.const bytes _{i128} ⁻¹ (bytes _{i8} (n) ¹⁶)
'v128.const' 'i16x8' (n:i16) ⁸	⇒	v128.const bytes _{i128} ⁻¹ (bytes _{i16} (n) ⁸)
'v128.const' 'i32x4' (n:i32) ⁴	⇒	v128.const bytes _{i128} ⁻¹ (bytes _{i32} (n) ⁴)
'v128.const' 'i64x2' (n:i64) ²	⇒	v128.const bytes _{i128} ⁻¹ (bytes _{i64} (n) ²)
'v128.const' 'f32x4' (z:f32) ⁴	⇒	v128.const bytes _{i128} ⁻¹ (bytes _{f32} (z) ⁴)
'v128.const' 'f64x2' (z:f64) ²	⇒	v128.const bytes _{i128} ⁻¹ (bytes _{f64} (z) ²)
'i8x16.shuffle' (laneidx:u8) ¹⁶	⇒	i8x16.shuffle laneidx ¹⁶
'i8x16.swizzle'	⇒	i8x16.swizzle
'i8x16.splat'	⇒	i8x16.splat
'i16x8.splat'	⇒	i16x8.splat
'i32x4.splat'	⇒	i32x4.splat
'i64x2.splat'	⇒	i64x2.splat
'f32x4.splat'	⇒	f32x4.splat
'f64x2.splat'	⇒	f64x2.splat
'i8x16.extract_lane_s' laneidx:u8	⇒	i8x16.extract_lane_s laneidx
'i8x16.extract_lane_u' laneidx:u8	⇒	i8x16.extract_lane_u laneidx
'i8x16.replace_lane' laneidx:u8	⇒	i8x16.replace_lane laneidx
'i16x8.extract_lane_s' laneidx:u8	⇒	i16x8.extract_lane_s laneidx
'i16x8.extract_lane_u' laneidx:u8	⇒	i16x8.extract_lane_u laneidx

6.5.10 Folded Instructions

Instructions can be written as S-expressions by grouping them into *folded* form. In that notation, an instruction is wrapped in parentheses and optionally includes nested folded instructions to indicate its operands.

In the case of [block instructions](#), the folded form omits the 'end' delimiter. For *if* instructions, both branches have to be wrapped into nested S-expressions, headed by the keywords 'then' and 'else'.

The set of all phrases defined by the following abbreviations recursively forms the auxiliary syntactic class *foldedinstr*. Such a folded instruction can appear anywhere a regular instruction can.

'(plaininstr foldedinstr*)'	≡	foldedinstr* plaininstr
'(block label blocktype instr*)'	≡	'block' label blocktype instr* 'end'
'(loop label blocktype instr*)'	≡	'loop' label blocktype instr* 'end'
'(if label blocktype foldedinstr* ('then instr ₁ *) ('else instr ₂ *)?)'	≡	foldedinstr* 'if' label blocktype instr ₁ * 'else' (instr ₂ *)? 'end'
'(try_table label blocktype catch* instr*)'	≡	'try_table' label blocktype catch* instr* 'end'

Note

For example, the instruction sequence

```
(local.get $x) (i32.const 2) i32.add (i32.const 3) i32.mul
```

can be folded into

```
(i32.mul (i32.add (local.get $x) (i32.const 2)) (i32.const 3))
```

Folded instructions are solely syntactic sugar, no additional syntactic or type-based checking is implied.

6.5.11 Expressions

Expressions are written as instruction sequences. No explicit ‘end’ keyword is included, since they only occur in bracketed positions.

$$\text{expr}_I ::= (in:\text{instr}_I)^* \Rightarrow in^*$$

6.6 Modules

6.6.1 Indices

Indices can be given either in raw numeric form or as symbolic **identifiers** when bound by a respective construct. Such identifiers are looked up in the suitable space of the **identifier context** I .

typeid_I	$::=$	$x:\text{u32}$	\Rightarrow	x
		$ $	$v:\text{id}$	$\Rightarrow x$ (if $I.\text{types}[x] = v$)
globalidx_I	$::=$	$x:\text{u32}$	\Rightarrow	x
		$ $	$v:\text{id}$	$\Rightarrow x$ (if $I.\text{globals}[x] = v$)
tagidx_I	$::=$	$x:\text{u32}$	\Rightarrow	x
		$ $	$v:\text{id}$	$\Rightarrow x$ (if $I.\text{tags}[x] = v$)
memidx_I	$::=$	$x:\text{u32}$	\Rightarrow	x
		$ $	$v:\text{id}$	$\Rightarrow x$ (if $I.\text{mems}[x] = v$)
tableidx_I	$::=$	$x:\text{u32}$	\Rightarrow	x
		$ $	$v:\text{id}$	$\Rightarrow x$ (if $I.\text{tables}[x] = v$)
funcidx_I	$::=$	$x:\text{u32}$	\Rightarrow	x
		$ $	$v:\text{id}$	$\Rightarrow x$ (if $I.\text{funcs}[x] = v$)
dataidx_I	$::=$	$x:\text{u32}$	\Rightarrow	x
		$ $	$v:\text{id}$	$\Rightarrow x$ (if $I.\text{datas}[x] = v$)
elemidx_I	$::=$	$x:\text{u32}$	\Rightarrow	x
		$ $	$v:\text{id}$	$\Rightarrow x$ (if $I.\text{elems}[x] = v$)
localidx_I	$::=$	$x:\text{u32}$	\Rightarrow	x
		$ $	$v:\text{id}$	$\Rightarrow x$ (if $I.\text{locals}[x] = v$)
labelidx_I	$::=$	$l:\text{u32}$	\Rightarrow	l
		$ $	$v:\text{id}$	$\Rightarrow l$ (if $I.\text{labels}[l] = v$)
$\text{fieldidx}_{I,x}$	$::=$	$i:\text{u32}$	\Rightarrow	i
		$ $	$v:\text{id}$	$\Rightarrow i$ (if $I.\text{fields}[x][i] = v$)

6.6.2 Tags

An tag definition can bind a symbolic tag **identifier**.

$$\text{tag}_I ::= \text{'(' 'tag' id? tt:tagtype_I ')} \Rightarrow \text{tag tt}$$

Abbreviations

Tags can be defined as **imports** or **exports** inline:

$$\begin{aligned} &\text{'(' 'tag' id? (' 'import' name_1 name_2 ') tagtype ')} \equiv \\ &\quad \text{'(' 'import' name_1 name_2 (' 'tag' id? tagtype ')} \text{' ')} \\ &\text{'(' 'tag' id? (' 'export' name ') ... ')} \equiv \\ &\quad \text{'(' 'export' name (' 'tag' id? ')} \text{' ')} \text{'(' 'tag' id? ... ')} \\ &\quad (\text{if id?} \neq \epsilon \wedge \text{id?} = \text{id?} \vee \text{id?} = \epsilon \wedge \text{id? fresh}) \end{aligned}$$

Note

The latter abbreviation can be applied repeatedly, if “...” contains additional export clauses. Consequently, a memory declaration can contain any number of exports, possibly followed by an import.

6.6.3 Globals

Global definitions can bind a symbolic [global identifier](#).

$$\text{global}_I ::= \text{'(' 'global' id? gt:globaltype}_I \text{ e:expr}_I \text{ ')} \Rightarrow \text{global gt e}$$

Abbreviations

Globals can be defined as [imports](#) or [exports](#) inline:

$$\begin{aligned} & \text{'(' 'global' id? (' 'import' name}_1 \text{ name}_2 \text{ ')} \text{ globaltype ')} \equiv \\ & \quad \text{'(' 'import' name}_1 \text{ name}_2 \text{ (' 'global' id? globaltype ')} \text{ ')} \\ & \text{'(' 'global' id? (' 'export' name ')} \dots \text{')} \equiv \\ & \quad \text{'(' 'export' name (' 'global' id' ')} \text{ ')} \text{ (' 'global' id' } \dots \text{ ')} \\ & \quad (\text{if id?} \neq \epsilon \wedge \text{id'} = \text{id?} \vee \text{id?} = \epsilon \wedge \text{id' fresh}) \end{aligned}$$
Note

The latter abbreviation can be applied repeatedly, if “...” contains additional export clauses. Consequently, a global declaration can contain any number of exports, possibly followed by an import.

6.6.4 Memories

Memory definitions can bind a symbolic [memory identifier](#).

$$\text{mem}_I ::= \text{'(' 'memory' id? mt:memtype}_I \text{ ')} \Rightarrow \text{memory mt}$$

Abbreviations

A [data segment](#) can be given inline with a memory definition, in which case its offset is 0 and the [limits](#) of the [memory type](#) are inferred from the length of the data, rounded up to [page size](#):

$$\begin{aligned} & \text{'(' 'memory' id? addrtype? (' 'data' b^n:datastring ')} \text{ ')} \equiv \\ & \quad \text{'(' 'memory' id? addrtype? m m ')} \\ & \quad \text{'(' 'data' (' 'memory' id' ')} \text{ (' 'addrtype' '.const' '0' ')} \text{ datastring ')} \\ & \quad (\text{if id?} \neq \epsilon \wedge \text{id'} = \text{id?} \vee \text{id?} = \epsilon \wedge \text{id' fresh,} \\ & \quad \text{if addrtype?} \neq \epsilon \wedge \text{addrtype'} = \text{addrtype?} \vee \text{addrtype?} = \epsilon \wedge \text{addrtype'} = \text{'i32'}, \\ & \quad m = \text{ceil}(n/64 \text{ Ki})) \end{aligned}$$

Memories can be defined as [imports](#) or [exports](#) inline:

$$\begin{aligned} & \text{'(' 'memory' id? (' 'import' name}_1 \text{ name}_2 \text{ ')} \text{ memtype ')} \equiv \\ & \quad \text{'(' 'import' name}_1 \text{ name}_2 \text{ (' 'memory' id? memtype ')} \text{ ')} \\ & \text{'(' 'memory' id? (' 'export' name ')} \dots \text{')} \equiv \\ & \quad \text{'(' 'export' name (' 'memory' id' ')} \text{ ')} \text{ (' 'memory' id' } \dots \text{ ')} \\ & \quad (\text{if id?} \neq \epsilon \wedge \text{id'} = \text{id?} \vee \text{id?} = \epsilon \wedge \text{id' fresh}) \end{aligned}$$

Note

The latter abbreviation can be applied repeatedly, if “...” contains additional export clauses. Consequently, a memory declaration can contain any number of exports, possibly followed by an import.

6.6.5 Tables

Table definitions can bind a symbolic [table identifier](#).

$$\text{table}_I ::= \text{'(' 'table' id? tt:tabletype}_I \text{ e:expr}_I \text{ ')} \Rightarrow \text{table tt e}$$
Abbreviations

A table’s initialization [expression](#) can be omitted, in which case it defaults to `ref.null`:

$$\text{'(' 'table' id? tabletype ')} \equiv \text{'(' 'table' id? tabletype '(' ref.null ht ')} \text{' (if tabletype = addrtype? limits '(' 'ref' 'null'? ht '))}$$

An [element segment](#) can be given inline with a table definition, in which case its offset is 0 and the [limits](#) of the [table type](#) are inferred from the length of the given segment:

$$\begin{aligned} &\text{'(' 'table' id? addrtype? reftype '(' 'elem' expr^n: \text{list}(\text{elemexpr}) \text{' ')} \text{'} \equiv \\ &\quad \text{'(' 'table' id? addrtype? n n reftype ')} \\ &\quad \text{'(' 'elem' '(' 'table' id? ')} \text{'(' addrtype? .const '0' ')} \text{ reftype list}(\text{elemexpr}) \text{' ')} \\ &\quad \text{(if id?} \neq \epsilon \wedge \text{id' = id?} \vee \text{id?} = \epsilon \wedge \text{id' fresh,} \\ &\quad \text{if addrtype?} \neq \epsilon \wedge \text{addrtype' = addrtype?} \vee \text{addrtype?} = \epsilon \wedge \text{addrtype' = 'i32'}) \\ \\ &\text{'(' 'table' id? addrtype? reftype '(' 'elem' x^n: \text{list}(\text{funcidx}) \text{' ')} \text{'} \equiv \\ &\quad \text{'(' 'table' id? addrtype? n n reftype ')} \\ &\quad \text{'(' 'elem' '(' 'table' id? ')} \text{'(' addrtype? .const '0' ')} \text{ reftype list}(\text{'(' 'ref.func' funcidx ')} \text{' ')} \\ &\quad \text{(if id?} \neq \epsilon \wedge \text{id' = id?} \vee \text{id?} = \epsilon \wedge \text{id' fresh,} \\ &\quad \text{if addrtype?} \neq \epsilon \wedge \text{addrtype' = addrtype?} \vee \text{addrtype?} = \epsilon \wedge \text{addrtype' = 'i32'}) \end{aligned}$$

Tables can be defined as [imports](#) or [exports](#) inline:

$$\begin{aligned} &\text{'(' 'table' id? '(' 'import' name}_1 \text{ name}_2 \text{ ')} \text{ tabletype ')} \equiv \\ &\quad \text{'(' 'import' name}_1 \text{ name}_2 \text{ '(' 'table' id? tabletype ')} \text{' ')} \\ \\ &\text{'(' 'table' id? '(' 'export' name ')} \text{ ... ')} \equiv \\ &\quad \text{'(' 'export' name '(' 'table' id? ')} \text{' ')} \text{'(' 'table' id? ... ')} \\ &\quad \text{(if id?} \neq \epsilon \wedge \text{id' = id?} \vee \text{id?} = \epsilon \wedge \text{id' fresh}) \end{aligned}$$
Note

The latter abbreviation can be applied repeatedly, if “...” contains additional export clauses. Consequently, a table declaration can contain any number of exports, possibly followed by an import.

6.6.6 Functions

Function definitions can bind a symbolic [function identifier](#), and [local identifiers](#) for its [parameters](#) and [locals](#).

$$\begin{aligned} \text{func}_I &::= \text{'(' 'func' id? x, I': \text{typeuse}_I \text{ (loc:local}_I \text{)* (in:instr}_{I''} \text{)* ')} \\ &\quad \Rightarrow \text{func x loc* in*} \\ &\quad \text{(if } I'' = I \oplus I' \oplus \{\text{locals id}(\text{local})^*\} \text{ well-formed)} \\ \\ \text{local}_I &::= \text{'(' 'local' id? t: \text{valtype}_I \text{ ')} \Rightarrow \text{local t} \end{aligned}$$

The definition of the local **identifier context** I'' uses the following auxiliary function to extract optional identifiers from locals:

$$\text{id}((\text{'local' id?} \dots \text{'})) = \text{id?}$$

Note

The **well-formedness** condition on I'' ensures that parameters and locals do not contain duplicate identifiers.

Abbreviations

Multiple anonymous locals may be combined into a single declaration:

$$(\text{'local' valtype*}) \equiv ((\text{'local' valtype}))^*$$

Functions can be defined as **imports** or **exports** inline:

$$\begin{aligned} (\text{'func' id?} (\text{'import' name}_1 \text{ name}_2 \text{'}) \text{ typeuse } \text{'}) &\equiv \\ &(\text{'import' name}_1 \text{ name}_2 (\text{'func' id?} \text{ typeuse } \text{'}) \text{'}) \\ (\text{'func' id?} (\text{'export' name } \text{'}) \dots \text{'}) &\equiv \\ &(\text{'export' name } (\text{'func' id?} \text{'}) \text{'}) (\text{'func' id?} \dots \text{'}) \\ &(\text{if id?} \neq \epsilon \wedge \text{id'} = \text{id?} \vee \text{id?} = \epsilon \wedge \text{id' fresh}) \end{aligned}$$

Note

The latter abbreviation can be applied repeatedly, if “...” contains additional export clauses. Consequently, a function declaration can contain any number of exports, possibly followed by an import.

6.6.7 Data Segments

Data segments allow for an optional **memory index** to identify the memory to initialize. The data is written as a **string**, which may be split up into a possibly empty sequence of individual string literals.

$$\begin{aligned} \text{data}_I &::= (\text{'data' id? } b^* \text{:datastring } \text{'}) \\ &\Rightarrow \text{data } b^* \text{ passive} \\ &| (\text{'data' id? } x \text{:memuse}_I (\text{'offset' } e \text{:expr}_I \text{'}) b^* \text{:datastring } \text{'}) \\ &\Rightarrow \text{data } b^* \text{ active } x \text{ } e \\ \text{datastring} &::= (b^* \text{:string})^* \Rightarrow \bigoplus((b^*)^*) \\ \text{memuse}_I &::= (\text{'memory' } x \text{:memidx}_I \text{'}) \Rightarrow x \end{aligned}$$

Note

In the current version of WebAssembly, the only valid memory index is 0 or a symbolic **memory identifier** resolving to the same value.

Abbreviations

As an abbreviation, a single **folded instruction** may occur in place of the offset of an active data segment:

$$(\text{'foldedinstr' }) \equiv (\text{'offset' instr } \text{'})$$

Also, a memory use can be omitted, defaulting to 0.

$$\epsilon \equiv (\text{'memory' '0' })$$

As another abbreviation, data segments may also be specified inline with **memory** definitions; see the respective section.

6.6.8 Element Segments

Element segments allow for an optional [table index](#) to identify the table to initialize.

```

elemI      ::=  '(' 'elem' id? (et,e*):elemIlistI ')'
                ⇒  elem et e* passive
                |  '(' 'elem' id? x:tableuseI '(' 'offset' e':exprI ')' (et,e*):elemIlistI ')'
                ⇒  elem et e* active x e'
                '(' 'elem' id? 'declare' (et,y*):elemIlistI ')'
                ⇒  elem et e* declare
elemIlistI ::=  t:reftypeI e*:list(elemIexprI)      ⇒  (t,ee*)
elemIexprI ::=  '(' 'item' e:exprI ')' ⇒  e
tableuseI  ::=  '(' 'table' x:tableidxI ')' ⇒  x

```

Abbreviations

As an abbreviation, a single [folded instruction](#) may occur in place of the offset of an active element segment or as an element expression:

```

('foldedinstr') ≡ '(' 'offset' instr ')'
('foldedinstr') ≡ '(' 'item' instr ')'

```

Also, the element list may be written as just a sequence of [function indices](#):

```

'func' list(funcidxI) ≡ '(' 'ref' 'func' list('(' 'ref.func' funcidxI ')')

```

A table use can be omitted, defaulting to 0. Furthermore, for backwards compatibility with earlier versions of WebAssembly, if the table use is omitted, the 'func' keyword can be omitted as well.

```

ε ≡ '(' 'table' '0' ')'
('elem' id? '(' 'offset' exprI ')' list(funcidxI')) ≡ '(' 'elem' id? '(' 'table' '0' ')' '(' 'offset' exprI ')' 'func' list(funcidxI ')')

```

As another abbreviation, element segments may also be specified inline with [table](#) definitions; see the respective section.

6.6.9 Start Function

A [start function](#) is defined in terms of its index.

```

startI ::=  '(' 'start' x:funcidxI ')' ⇒  start x

```

Note

At most one start function may occur in a module, which is ensured by a suitable side condition on the [module](#) grammar.

6.6.10 Imports

The [external type](#) in imports can bind a symbolic tag, global, memory, or function [identifier](#).

```

importI ::=  '(' 'import' nm1:name nm2:name xx:externtypeI ')'
                ⇒  import nm1 nm2 xx

```

Abbreviations

As an abbreviation, imports may also be specified inline with [tag](#), [global](#), [memory](#), [table](#), or [function](#) definitions; see the respective sections.

6.6.11 Exports

The syntax for exports mirrors their [abstract syntax](#) directly.

<code>export_I</code>	<code>::=</code>	<code>(' 'export' nm:name xx:externidx_I ')</code>	\Rightarrow	<code>export nm xx</code>
<code>externidx_I</code>	<code>::=</code>	<code>(' 'tag' x:tagidx_I ')</code>	\Rightarrow	<code>tag x</code>
		<code> (' 'global' x:globalidx_I ')</code>	\Rightarrow	<code>global x</code>
		<code> (' 'memory' x:memidx_I ')</code>	\Rightarrow	<code>memory x</code>
		<code> (' 'table' x:tableidx_I ')</code>	\Rightarrow	<code>table x</code>
		<code> (' 'func' x:funcidx_I ')</code>	\Rightarrow	<code>func x</code>

Abbreviations

As an abbreviation, exports may also be specified inline with [tag](#), [global](#), [memory](#), [table](#), or [function](#) definitions; see the respective sections.

6.6.12 Modules

A module consists of a sequence of fields that can occur in any order. All definitions and their respective bound [identifiers](#) scope over the entire module, including the text preceding them.

A module may optionally bind an [identifier](#) that names the module. The name serves a documentary role only.

Note

Tools may include the module name in the [name section](#) of the [binary format](#).

<code>module</code>	<code>::=</code>	<code>(' 'module' id? (m:modulefield_I)* ')</code>	\Rightarrow	$\bigoplus m^*$
		(if $I = \bigoplus \text{idc}(\text{modulefield})^*$ well-formed)		
<code>modulefield_I</code>	<code>::=</code>	<code>ty::rectype_I</code>	\Rightarrow	<code>module ty*</code>
		<code> im:import_I</code>	\Rightarrow	<code>module im</code>
		<code> tg:tag_I</code>	\Rightarrow	<code>module tg</code>
		<code> gl:global_I</code>	\Rightarrow	<code>module gl</code>
		<code> me:mem_I</code>	\Rightarrow	<code>module me</code>
		<code> ta:table_I</code>	\Rightarrow	<code>module ta</code>
		<code> fn:func_I</code>	\Rightarrow	<code>module fn</code>
		<code> da:data_I</code>	\Rightarrow	<code>module da</code>
		<code> el:elem_I</code>	\Rightarrow	<code>module el</code>
		<code> st:start_I</code>	\Rightarrow	<code>module st</code>
		<code> ex:export_I</code>	\Rightarrow	<code>module ex</code>

where $\bigoplus m^*$ is the [module](#) formed by the repeated concatenation of the individual field sequences in order. The following restrictions are imposed on this composition: $m_1 \oplus m_2$ is defined if and only if

- $start_1^? = \epsilon \vee start_2^? = \epsilon$
- $tag_1^* = global_1^* = mem_1^* = table_1^* = func_1^* = \epsilon \vee import_2^* = \epsilon$

Note

The first condition ensures that there is at most one start function. The second condition enforces that all [imports](#) must occur before any regular definition of a [tag](#), [global](#), [memory](#), [table](#), or [function](#), thereby maintaining the ordering of the respective [index spaces](#).

The [well-formedness](#) condition on I in the grammar for [module](#) ensures that no namespace contains duplicate identifiers.

The definition of the initial **identifier context** I uses the following auxiliary definition which maps each relevant definition to a singular context with one (possibly empty) identifier:

<code>idc(('rec' typedef* '))</code>	$= \bigoplus \text{idc}(\text{typedef})^*$
<code>idc(('type' $v^?:\text{id}^?$ subtype '))</code>	$= \{\text{types}(v^?), \text{fields idf}(\text{subtype}), \text{typedefs } st\}$
<code>idc(('tag' $v^?:\text{id}^?$... '))</code>	$= \{\text{tags}(v^?)\}$
<code>idc(('global' $v^?:\text{id}^?$... '))</code>	$= \{\text{globals}(v^?)\}$
<code>idc(('memory' $v^?:\text{id}^?$... '))</code>	$= \{\text{mems}(v^?)\}$
<code>idc(('table' $v^?:\text{id}^?$... '))</code>	$= \{\text{tables}(v^?)\}$
<code>idc(('func' $v^?:\text{id}^?$... '))</code>	$= \{\text{funcs}(v^?)\}$
<code>idc(('data' $v^?:\text{id}^?$... '))</code>	$= \{\text{datas}(v^?)\}$
<code>idc(('elem' $v^?:\text{id}^?$... '))</code>	$= \{\text{elems}(v^?)\}$
<code>idc(('import' ... ('func' $v^?:\text{id}^?$... ')) '))</code>	$= \{\text{funcs}(v^?)\}$
<code>idc(('import' ... ('table' $v^?:\text{id}^?$... ')) '))</code>	$= \{\text{tables}(v^?)\}$
<code>idc(('import' ... ('memory' $v^?:\text{id}^?$... ')) '))</code>	$= \{\text{mems}(v^?)\}$
<code>idc(('import' ... ('global' $v^?:\text{id}^?$... ')) '))</code>	$= \{\text{globals}(v^?)\}$
<code>idc(('... '))</code>	$= \{\}$
<code>idf(('sub' ... comptype '))</code>	$= \text{idf}(\text{comptype})$
<code>idf(('struct' $T\text{field}^*$ '))</code>	$= \bigoplus \text{idf}(\text{field})^*$
<code>idf(('array' ... '))</code>	$= \epsilon$
<code>idf(('func' ... '))</code>	$= \epsilon$
<code>idf(('field' $v^?:\text{id}^?$... '))</code>	$= v^?$

Abbreviations

In a source file, the toplevel (module ...) surrounding the module body may be omitted.

$$\text{modulefield}^* \equiv (' \text{'module' modulefield}^* ')$$

7.1 Embedding

A WebAssembly implementation will typically be *embedded* into a *host* environment. An *embedder* implements the connection between such a host environment and the WebAssembly semantics as defined in the main body of this specification. An embedder is expected to interact with the semantics in well-defined ways.

This section defines a suitable interface to the WebAssembly semantics in the form of entry points through which an embedder can access it. The interface is intended to be complete, in the sense that an embedder does not need to reference other functional parts of the WebAssembly specification directly.

Note

On the other hand, an embedder does not need to provide the host environment with access to all functionality defined in this interface. For example, an implementation may not support [parsing](#) of the [text format](#).

7.1.1 Types

In the description of the embedder interface, syntactic classes from the [abstract syntax](#) and the [runtime's abstract machine](#) are used as names for variables that range over the possible objects from that class. Hence, these syntactic classes can also be interpreted as types.

For numeric parameters, notation like $i : u64$ is used to specify a symbolic name in addition to the respective value range.

7.1.2 Booleans

Interface operation that are predicates return Boolean values:

$$bool ::= false \mid true$$

7.1.3 Exceptions and Errors

Invoking an exported function may throw or propagate exceptions, expressed by an auxiliary syntactic class:

$$exception ::= exception \text{ } exnaddr$$

The exception address $exnaddr$ identifies the exception thrown.

Failure of an interface operation is also indicated by an auxiliary syntactic class:

$$\text{error} ::= \text{error}$$

In addition to the error conditions specified explicitly in this section, such as invalid arguments or **exceptions** and **traps** resulting from **execution**, implementations may also return errors when specific **implementation limitations** are reached.

Note

Errors are abstract and unspecific with this definition. Implementations can refine it to carry suitable classifications and diagnostic messages.

7.1.4 Pre- and Post-Conditions

Some operations state *pre-conditions* about their arguments or *post-conditions* about their results. It is the embedder's responsibility to meet the pre-conditions. If it does, the post conditions are guaranteed by the semantics.

In addition to pre- and post-conditions explicitly stated with each operation, the specification adopts the following conventions for **runtime objects** (*store*, *moduleinst*, *addresses*):

- Every runtime object passed as a parameter must be **valid** per an implicit pre-condition.
- Every runtime object returned as a result is **valid** per an implicit post-condition.

Note

As long as an embedder treats runtime objects as abstract and only creates and manipulates them through the interface defined here, all implicit pre-conditions are automatically met.

7.1.5 Store

`store_init() : store`

1. Return the empty **store**.

$$\text{store_init()} = \{\}$$

7.1.6 Modules

`module_decode(byte*) : module | error`

1. If there exists a derivation for the **byte** sequence *byte** as a **module** according to the **binary grammar** for **modules**, yielding a **module** *m*, then return *m*.
2. Else, return **error**.

$$\begin{aligned} \text{module_decode}(b^*) &= m && (\text{if } \text{module} \xRightarrow{*} m:b^*) \\ \text{module_decode}(b^*) &= \text{error} && (\text{otherwise}) \end{aligned}$$

`module_parse(char*) : module | error`

1. If there exists a derivation for the **source** *char** as a **module** according to the **text grammar** for **modules**, yielding a **module** *m*, then return *m*.
2. Else, return **error**.

$$\begin{aligned} \text{module_parse}(c^*) &= m && (\text{if } \text{module} \xRightarrow{*} m:c^*) \\ \text{module_parse}(c^*) &= \text{error} && (\text{otherwise}) \end{aligned}$$

$\text{module_validate}(\text{module}) : \text{error}^?$

1. If module is valid, then return nothing.
2. Else, return error .

$$\begin{aligned} \text{module_validate}(m) &= \epsilon && (\text{if } \vdash m : \text{externtype}^* \rightarrow \text{externtype}'^*) \\ \text{module_validate}(m) &= \text{error} && (\text{otherwise}) \end{aligned}$$

$\text{module_instantiate}(\text{store}, \text{module}, \text{externaddr}^*) : (\text{store}, \text{moduleinst} \mid \text{exception} \mid \text{error})$

1. Try instantiating module in store with external addresses externaddr^* as imports:
 - a. If it succeeds with a module instance moduleinst , then let result be moduleinst .
 - b. Else, let result be error .
2. Return the new store paired with result .

$$\begin{aligned} \text{module_instantiate}(S, m, ev^*) &= (S', F.\text{module}) && (\text{if } \text{instantiate}(S, m, ev^*) \hookrightarrow^* S'; F; \epsilon) \\ \text{module_instantiate}(S, m, ev^*) &= (S', \text{error}) && (\text{otherwise, if } \text{instantiate}(S, m, ev^*) \hookrightarrow^* S'; F; \text{result}) \end{aligned}$$

Note

The store may be modified even in case of an error.

$\text{module_imports}(\text{module}) : (\text{name}, \text{name}, \text{externtype})^*$

1. Pre-condition: module is valid with the external import types externtype^* and external export types $\text{externtype}'^*$.
2. Let import^* be the imports of module .
3. Assert: the length of import^* equals the length of externtype^* .
4. For each import_i in import^* and corresponding externtype_i in externtype^* , do:
 - a. Let $\text{import } nm_{i1} \text{ } nm_{i2} \text{ } xt_i$ be the deconstruction of import_i .
 - b. Let result_i be the triple $(nm_{i1}, nm_{i2}, \text{externtype}_i)$.
5. Return the concatenation of all result_i , in index order.
6. Post-condition: each externtype_i is valid under the empty context.

$$\begin{aligned} \text{module_imports}(m) &= (nm_1, nm_2, \text{externtype})^* \\ &\quad (\text{if } (\text{import } nm_1 \text{ } nm_2 \text{ } xt^*)^* \in m \wedge \vdash m : \text{externtype}^* \rightarrow \text{externtype}'^*) \end{aligned}$$

$\text{module_exports}(\text{module}) : (\text{name}, \text{externtype})^*$

1. Pre-condition: module is valid with the external import types externtype^* and external export types $\text{externtype}'^*$.
2. Let export^* be the exports of module .
3. Assert: the length of export^* equals the length of $\text{externtype}'^*$.
4. For each export_i in export^* and corresponding $\text{externtype}'_i$ in $\text{externtype}'^*$, do:
 - a. Let $\text{export } nm_i \text{ } \text{externidx}_i$ be the deconstruction of export_i .
 - b. Let result_i be the pair $(nm_i, \text{externtype}'_i)$.
5. Return the concatenation of all result_i , in index order.

6. Post-condition: each $externtype'_i$ is valid under the empty context.

$$\begin{aligned} \text{module_exports}(m) &= (\\ \text{mathit{nm}, } &\text{externtype}')^* \\ &(\text{if } (\text{export } nm \ x^*)^* \in m \wedge \vdash m : \text{externtype}^* \rightarrow \text{externtype}'^*) \end{aligned}$$

7.1.7 Module Instances

$\text{instance_export}(\text{moduleinst}, \text{name}) : \text{externaddr} \mid \text{error}$

1. Assert: due to validity of the module instance moduleinst , all its export names are different.
2. If there exists an exportinst_i in $\text{moduleinst.exports}$ such that $\text{name } \text{exportinst}_i.\text{name}$ equals name , then:
 - a. Return the external address $\text{exportinst}_i.\text{addr}$.
3. Else, return error.

$$\begin{aligned} \text{instance_export}(m, \text{name}) &= m.\text{exports}[i].\text{addr} && (\text{if } m.\text{exports}[i].\text{name} = \text{name}) \\ \text{instance_export}(m, \text{name}) &= \text{error} && (\text{otherwise}) \end{aligned}$$

7.1.8 Functions

$\text{func_alloc}(\text{store}, \text{deftype}, \text{hostfunc}) : (\text{store}, \text{funcaddr})$

1. Pre-condition: the defined type deftype is valid under the empty context and expands to a function type.
2. Let funcaddr be the result of allocating a host function in store with defined type deftype , host function code hostfunc and an empty module instance.
3. Return the new store paired with funcaddr .

$$\text{func_alloc}(S, dt, \text{code}) = (S', a) \quad (\text{if } \text{allocfunc}(S, dt, \text{code}, \{\}) = S', a)$$

Note

This operation assumes that hostfunc satisfies the pre- and post-conditions required for a function instance with type deftype .

Regular (non-host) function instances can only be created indirectly through module instantiation.

$\text{func_type}(\text{store}, \text{funcaddr}) : \text{deftype}$

1. Let deftype be the definedn type $S.\text{funcs}[a].\text{type}$.
2. Return deftype .
3. Post-condition: the returned defined type is valid and expands to a function type.

$$\text{func_type}(S, a) = S.\text{funcs}[a].\text{type}$$

$\text{func_invoke}(\text{store}, \text{funcaddr}, \text{val}^*) : (\text{store}, \text{val}^* \mid \text{exception} \mid \text{error})$

1. Try invoking the function funcaddr in store with values val^* as arguments:
 - a. If it succeeds with values val'^* as results, then let result be val'^* .
 - b. Else if the outcome is an exception with a thrown exception ref.exn exnaddr as the result, then let result be exception exnaddr

- c. Else it has trapped, hence let *result* be **error**.
2. Return the new store paired with *result*.

$$\begin{aligned}
\text{func_invoke}(S, a, v^*) &= (S', v'^*) && (\text{if } \text{invoke}(S, a, v^*) \hookrightarrow *S'; F; v'^*) \\
\text{func_invoke}(S, a, v^*) &= (S', \text{exception } a') && (\text{if } \text{invoke}(S, a, v^*) \hookrightarrow *S'; F; (\text{ref.exn } a') \text{ throw_ref}) \\
\text{func_invoke}(S, a, v^*) &= (S', \text{error}) && (\text{if } \text{invoke}(S, a, v^*) \hookrightarrow *S'; F; \text{trap})
\end{aligned}$$

Note

The store may be modified even in case of an error.

7.1.9 Tables

$\text{table_alloc}(\text{store}, \text{tabletype}, \text{ref}) : (\text{store}, \text{tableaddr})$

1. Pre-condition: the *tabletype* is **valid** under the empty context.
2. Let *tableaddr* be the result of **allocating** a table in *store* with table type *tabletype* and initialization value *ref*.
3. Return the new store paired with *tableaddr*.

$$\text{table_alloc}(S, tt, r) = (S', a) \quad (\text{if } \text{alloctable}(S, tt, r) = S', a)$$

$\text{table_type}(\text{store}, \text{tableaddr}) : \text{tabletype}$

1. Return *S.tables[a].type*.
2. Post-condition: the returned table type is **valid** under the empty context.

$$\text{table_type}(S, a) = S.\text{tables}[a].\text{type}$$

$\text{table_read}(\text{store}, \text{tableaddr}, i : u64) : \text{ref} \mid \text{error}$

1. Let *ti* be the table instance *store.tables[tableaddr]*.
2. If *i* is larger than or equal to the length of *ti.elem*, then return **error**.
3. Else, return the **reference value** *ti.elem[i]*.

$$\begin{aligned}
\text{table_read}(S, a, i) &= r && (\text{if } S.\text{tables}[a].\text{elem}[i] = r) \\
\text{table_read}(S, a, i) &= \text{error} && (\text{otherwise})
\end{aligned}$$

$\text{table_write}(\text{store}, \text{tableaddr}, i : u64, \text{ref}) : \text{store} \mid \text{error}$

1. Let *ti* be the table instance *store.tables[tableaddr]*.
2. If *i* is larger than or equal to the length of *ti.elem*, then return **error**.
3. Replace *ti.elem[i]* with the **reference value** *ref*.
4. Return the updated store.

$$\begin{aligned}
\text{table_write}(S, a, i, r) &= S' && (\text{if } S' = S \text{ with } \text{tables}[a].\text{elem}[i] = r) \\
\text{table_write}(S, a, i, r) &= \text{error} && (\text{otherwise})
\end{aligned}$$

$\text{table_size}(\text{store}, \text{tableaddr}) : u64$

1. Return the length of *store.tables[tableaddr].elem*.

$$\text{table_size}(S, a) = n \quad (\text{if } |S.\text{tables}[a].\text{elem}| = n)$$

$\text{table_grow}(\text{store}, \text{tableaddr}, n : u64, \text{ref}) : \text{store} \mid \text{error}$

1. Try growing the table instance $\text{store.tables}[\text{tableaddr}]$ by n elements with initialization value ref :
 - a. If it succeeds, return the updated store.
 - b. Else, return **error**.

$$\begin{aligned} \text{table_grow}(S, a, n, r) &= S' && (\text{if } S' = S \text{ with } \text{tables}[a] = \text{growtable}(S.\text{tables}[a], n, r)) \\ \text{table_grow}(S, a, n, r) &= \text{error} && (\text{otherwise}) \end{aligned}$$

7.1.10 Memories

$\text{mem_alloc}(\text{store}, \text{memtype}) : (\text{store}, \text{memaddr})$

1. Pre-condition: the *memtype* is valid under the empty context.
2. Let *memaddr* be the result of allocating a memory in *store* with memory type *memtype*.
3. Return the new store paired with *memaddr*.

$$\text{mem_alloc}(S, mt) = (S', a) \quad (\text{if } \text{allocmem}(S, mt) = S', a)$$

$\text{mem_type}(\text{store}, \text{memaddr}) : \text{memtype}$

1. Return $S.\text{mems}[a].\text{type}$.
2. Post-condition: the returned memory type is valid under the empty context.

$$\text{mem_type}(S, a) = S.\text{mems}[a].\text{type}$$

$\text{mem_read}(\text{store}, \text{memaddr}, i : u64) : \text{byte} \mid \text{error}$

1. Let *mi* be the memory instance $\text{store.mems}[\text{memaddr}]$.
2. If *i* is larger than or equal to the length of *mi.bytes*, then return **error**.
3. Else, return the byte $\text{mi.bytes}[i]$.

$$\begin{aligned} \text{mem_read}(S, a, i) &= b && (\text{if } S.\text{mems}[a].\text{bytes}[i] = b) \\ \text{mem_read}(S, a, i) &= \text{error} && (\text{otherwise}) \end{aligned}$$

$\text{mem_write}(\text{store}, \text{memaddr}, i : u64, \text{byte}) : \text{store} \mid \text{error}$

1. Let *mi* be the memory instance $\text{store.mems}[\text{memaddr}]$.
2. If *i* is larger than or equal to the length of *mi.bytes*, then return **error**.
3. Replace $\text{mi.bytes}[i]$ with *byte*.
4. Return the updated store.

$$\begin{aligned} \text{mem_write}(S, a, i, b) &= S' && (\text{if } S' = S \text{ with } \text{mems}[a].\text{bytes}[i] = b) \\ \text{mem_write}(S, a, i, b) &= \text{error} && (\text{otherwise}) \end{aligned}$$

$\text{mem_size}(\text{store}, \text{memaddr}) : u64$

1. Return the length of $\text{store.mems}[\text{memaddr}].\text{bytes}$ divided by the page size.

$$\text{mem_size}(S, a) = n \quad (\text{if } |S.\text{mems}[a].\text{bytes}| = n \cdot 64 \text{ Ki})$$

$\text{mem_grow}(\text{store}, \text{memaddr}, n : u64) : \text{store} \mid \text{error}$

1. Try growing the memory instance $\text{store.mems}[\text{memaddr}]$ by n pages:
 - a. If it succeeds, return the updated store.
 - b. Else, return error .

$$\begin{aligned} \text{mem_grow}(S, a, n) &= S' && (\text{if } S' = S \text{ with } \text{mems}[a] = \text{growmem}(S.\text{mems}[a], n)) \\ \text{mem_grow}(S, a, n) &= \text{error} && (\text{otherwise}) \end{aligned}$$

7.1.11 Tags

$\text{tag_alloc}(\text{store}, \text{tagtype}) : (\text{store}, \text{tagaddr})$

1. Pre-condition: tagtype is valid.
2. Let tagaddr be the result of allocating a tag in store with tag type tagtype .
3. Return the new store paired with tagaddr .

$$\text{tag_alloc}(S, tt) = (S', a) \quad (\text{if } \text{alloc_tag}(S, tt) = S', a)$$

$\text{tag_type}(\text{store}, \text{tagaddr}) : \text{tagtype}$

1. Return $S.\text{tags}[a].\text{type}$.
2. Post-condition: the returned tag type is valid.

$$\text{tag_type}(S, a) = S.\text{tags}[a].\text{type}$$

7.1.12 Exceptions

$\text{exn_alloc}(\text{store}, \text{tagaddr}, \text{val}^*) : (\text{store}, \text{exnaddr})$

1. Pre-condition: tagaddr is an allocated tag address.
2. Let exnaddr be the result of allocating an exception instance in store with tag address tagaddr and initialization values val^* .
3. Return the new store paired with exnaddr .

$$\text{exn_alloc}(S, \text{tagaddr}, \text{val}^*) = (S \oplus \{\text{exns } \text{exninst}\}, |S.\text{exns}|) \quad (\text{if } \text{exninst} = \{\text{tag } \text{tagaddr}, \text{fields } \text{val}^*\})$$

$\text{exn_tag}(\text{store}, \text{exnaddr}) : \text{tagaddr}$

1. Let exninst be the exception instance $\text{store.exns}[\text{exnaddr}]$.
2. Return the tag address exninst.tag .

$$\text{exn_tag}(S, a) = \text{exninst.tag} \quad (\text{if } \text{exninst} = S.\text{exns}[a])$$

$\text{exn_read}(\text{store}, \text{exnaddr}) : \text{val}^*$

1. Let exninst be the exception instance $\text{store.exns}[\text{exnaddr}]$.
2. Return the values exninst.fields .

$$\text{exn_read}(S, a) = \text{exninst.fields} \quad (\text{if } \text{exninst} = S.\text{exns}[a])$$

7.1.13 Globals

$\text{global_alloc}(\text{store}, \text{globaltype}, \text{val}) : (\text{store}, \text{globaladdr})$

1. Pre-condition: the *globaltype* is valid under the empty context.
2. Let *globaladdr* be the result of allocating a global in *store* with global type *globaltype* and initialization value *val*.
3. Return the new store paired with *globaladdr*.

$$\text{global_alloc}(S, gt, v) = (S', a) \quad (\text{if } \text{allocglobal}(S, gt, v) = S', a)$$

$\text{global_type}(\text{store}, \text{globaladdr}) : \text{globaltype}$

1. Return $S.\text{globals}[a].\text{type}$.
2. Post-condition: the returned global type is valid under the empty context.

$$\text{global_type}(S, a) = S.\text{globals}[a].\text{type}$$

$\text{global_read}(\text{store}, \text{globaladdr}) : \text{val}$

1. Let *gi* be the global instance $\text{store.globals}[\text{globaladdr}]$.
2. Return the value *gi.value*.

$$\text{global_read}(S, a) = v \quad (\text{if } S.\text{globals}[a].\text{value} = v)$$

$\text{global_write}(\text{store}, \text{globaladdr}, \text{val}) : \text{store} \mid \text{error}$

1. Let *gi* be the global instance $\text{store.globals}[\text{globaladdr}]$.
2. Let *mut t* be the structure of the global type *gi.type*.
3. If *mut* is empty, then return *error*.
4. Replace *gi.value* with the value *val*.
5. Return the updated store.

$$\begin{aligned} \text{global_write}(S, a, v) &= S' && (\text{if } S.\text{globals}[a].\text{type} = \text{mut } t \wedge S' = S \text{ with } \text{globals}[a].\text{value} = v) \\ \text{global_write}(S, a, v) &= \text{error} && (\text{otherwise}) \end{aligned}$$

7.1.14 Values

$\text{ref_type}(\text{store}, \text{ref}) : \text{reftype}$

1. Pre-condition: the reference *ref* is valid under store *S*.
2. Return the reference type *t* with which *ref* is valid.
3. Post-condition: the returned reference type is valid under the empty context.

$$\text{ref_type}(S, r) = t \quad (\text{if } S \vdash r : t)$$

Note

In future versions of WebAssembly, not all references may carry precise type information at run time. In such cases, this function may return a less precise supertype.

$\text{val_default}(\text{valtype}) : \text{val}$

1. If $\text{default}_{\text{valtype}}$ is not defined, then return *error*.
1. Else, return the value $\text{default}_{\text{valtype}}$.

$$\begin{aligned} \text{val_default}(t) &= v && (\text{if } \text{default}_t = v) \\ \text{val_default}(t) &= \text{error} && (\text{if } \text{default}_t = \epsilon) \end{aligned}$$

7.1.15 Matching

$\text{match_valtype}(\text{valtype}_1, \text{valtype}_2) : \text{bool}$

1. Pre-condition: the value types valtype_1 and valtype_2 are valid under the empty context.
2. If valtype_1 matches valtype_2 , then return *true*.
3. Else, return *false*.

$$\begin{aligned} \text{match_reftype}(t_1, t_2) &= \text{true} && (\text{if } \vdash t_1 \leq t_2) \\ \text{match_reftype}(t_1, t_2) &= \text{false} && (\text{otherwise}) \end{aligned}$$

$\text{match_externtype}(\text{externtype}_1, \text{externtype}_2) : \text{bool}$

1. Pre-condition: the extern types externtype_1 and externtype_2 are valid under the empty context.
2. If externtype_1 matches externtype_2 , then return *true*.
3. Else, return *false*.

$$\begin{aligned} \text{match_externtype}(et_1, et_2) &= \text{true} && (\text{if } \vdash et_1 \leq et_2) \\ \text{match_externtype}(et_1, et_2) &= \text{false} && (\text{otherwise}) \end{aligned}$$

7.2 Profiles

To enable the use of WebAssembly in as many environments as possible, *profiles* specify coherent language subsets that fit constraints imposed by common classes of host environments. A host platform can thereby decide to support the language only under a restricted profile, or even the intersection of multiple profiles.

7.2.1 Conventions

A profile modification is specified by decorating selected rules in the main body of this specification with a *profile annotation* that defines them as conditional on the choice of profile.

For that purpose, every profile defines a *profile marker*, an alphanumeric short-hand like ABC. A profile annotation of the form $[\text{!ABC XYZ}]$ on a rule indicates that this rule is *excluded* for either of the profiles whose marker is ABC or XYZ.

There are two ways of subsetting the language in a profile:

- *Syntactic*, by *omitting* a feature, in which case certain constructs are removed from the syntax altogether.
- *Semantic*, by *restricting* a feature, in which case certain constructs are still present but some behaviours are ruled out.

Syntax Annotations

To omit a construct from a profile syntactically, respective productions in the grammar of the *abstract syntax* are annotated with an associated profile marker. This is defined to have the following implications:

1. Any production in the *binary* or *textual* syntax that produces abstract syntax with a marked construct is omitted by extension.
2. Any *validation* or *execution* rule that handles a marked construct is omitted by extension.

The overall effect is that the respective construct is no longer part of the language under a respective profile.

Note

For example, a “busy” profile marked BUSY could rule out the `nop` instruction by marking the production for it in the abstract syntax as follows:

$$\begin{array}{lcl} \text{instr} & ::= & \dots \\ \text{[!BUSY]} & | & \text{nop} \\ & | & \text{unreachable} \end{array}$$

A rule may be annotated by multiple markers, which could be the case if a construct is in the intersection of multiple features.

Semantics Annotations

To restrict certain behaviours in a profile, individual `validation` or `reduction` rules or auxiliary definitions are annotated with an associated marker.

This has the consequence that the respective rule is no longer applicable under the given profile.

Note

For example, an “infinite” profile marked INF could define that growing memory never fails:

$$\begin{array}{lcl} S; F; (i32.\text{const } n) \text{ memory.grow } x & \hookrightarrow & S'; F; (i32.\text{const } sz) \\ & & (\text{if } F.\text{module.mems}[x] = a \\ & & \wedge sz = |S.\text{mems}[a].\text{datas}|/64 \text{ Ki} \\ & & \wedge S' = S \text{ with mems}[a] = \text{growmem}(S.\text{mems}[a], n)) \\ \text{[!INF]} \quad S; F; (i32.\text{const } n) \text{ memory.grow } x & \hookrightarrow & S; F; (i32.\text{const signed}_{32}^{-1}(-1)) \end{array}$$

Properties

All profiles are defined such that the following properties are preserved:

- All profiles represent syntactic and semantic subsets of the `full profile`, i.e., they do not *add* syntax or *alter* behaviour.
- All profiles are mutually compatible, i.e., no two profiles subset semantic behaviour in inconsistent or ambiguous ways, and any intersection of profiles preserves the properties described here.
- Profiles do not violate `soundness`, i.e., all `configurations` valid under that profile still have well-defined execution behaviour.

Note

Tools are generally expected to handle and produce code for the full profile by default. In particular, producers should not generate code that *depends* on specific profiles. Instead, all code should preserve correctness when executed under the full profile.

Moreover, profiles should be considered static and fixed for a given platform or ecosystem. Runtime conditioning on the “current” profile is not intended and should be avoided.

7.2.2 Defined Profiles

Note

The number of defined profiles is expected to remain small in the future. Profiles are intended for broad and permanent use cases only. In particular, profiles are not intended for language versioning.

Full Profile (FUL)

The *full* profile contains the complete language and all possible behaviours. It imposes no restrictions, i.e., all rules and definitions are active. All other profiles define sub-languages of this profile.

Deterministic Profile (DET)

The *deterministic* profile excludes all rules marked ^[!DET]. It defines a sub-language that does not exhibit any incidental non-deterministic behaviour:

- All NaN values generated by floating-point instructions are canonical and positive.
- All relaxed vector instructions have a fixed behaviour that does not depend on the implementation.

Even under this profile, the `memory.grow` and `table.grow` instructions technically remain *non-deterministic*, in order to be able to indicate resource exhaustion.

Note

In future versions of WebAssembly, new non-deterministic behaviour may be added to the language, such that the deterministic profile will induce additional restrictions.

7.3 Implementation Limitations

Implementations typically impose additional restrictions on a number of aspects of a WebAssembly module or execution. These may stem from:

- physical resource limits,
- constraints imposed by the embedder or its environment,
- limitations of selected implementation strategies.

This section lists allowed limitations. Where restrictions take the form of numeric limits, no minimum requirements are given, nor are the limits assumed to be concrete, fixed numbers. However, it is expected that all implementations have “reasonably” large limits to enable common applications.

Note

A conforming implementation is not allowed to leave out individual *features*. However, designated subsets of WebAssembly may be specified in the future.

7.3.1 Syntactic Limits

Structure

An implementation may impose restrictions on the following dimensions of a module:

- the number of `types` in a `module`
- the number of `functions` in a `module`, including imports
- the number of `tables` in a `module`, including imports
- the number of `memories` in a `module`, including imports

- the number of [globals](#) in a [module](#), including imports
- the number of [tags](#) in a [module](#), including imports
- the number of [element segments](#) in a [module](#)
- the number of [data segments](#) in a [module](#)
- the number of [imports](#) to a [module](#)
- the number of [exports](#) from a [module](#)
- the number of [sub types](#) in a [recursive type](#)
- the subtyping depth of a [sub type](#)
- the number of fields in a [structure type](#)
- the number of parameters in a [function type](#)
- the number of results in a [function type](#)
- the number of parameters in a [block type](#)
- the number of results in a [block type](#)
- the number of [locals](#) in a [function](#)
- the number of [instructions](#) in a [function body](#)
- the number of [instructions](#) in a [structured control instruction](#)
- the number of [structured control instructions](#) in a [function](#)
- the nesting depth of [structured control instructions](#)
- the number of [label indices](#) in a [br_table](#) instruction
- the number of instructions in a [constant expression](#)
- the length of the array in a [array.new_fixed](#) instruction
- the length of an [element segment](#)
- the length of a [data segment](#)
- the length of a [name](#)
- the range of [characters](#) in a [name](#)

If the limits of an implementation are exceeded for a given module, then the implementation may reject the [validation](#), compilation, or [instantiation](#) of that module with an embedder-specific error.

Note

The last item allows [embedders](#) that operate in limited environments without support for [Unicode](#)⁴⁸ to limit the names of [imports](#) and [exports](#) to common subsets like [ASCII](#)⁴⁹.

Binary Format

For a module given in [binary format](#), additional limitations may be imposed on the following dimensions:

- the size of a [module](#)
- the size of any [section](#)
- the size of an individual [function's code](#)
- the size of a [structured control instruction](#)

⁴⁸ <https://www.unicode.org/versions/latest/>

⁴⁹ <https://webstore.ansi.org/RecordDetail.aspx?sku=INCITS+4-1986%5bR2012%5d>

- the size of an individual [constant expression](#)'s instruction sequence
- the number of [sections](#)

Text Format

For a module given in [text format](#), additional limitations may be imposed on the following dimensions:

- the size of the [source text](#)
- the size of any syntactic element
- the size of an individual [token](#)
- the nesting depth of [folded instructions](#)
- the length of symbolic [identifiers](#)
- the range of literal [characters](#) allowed in the [source text](#)

7.3.2 Validation

An implementation may defer [validation](#) of individual [functions](#) until they are first [invoked](#).

If a function turns out to be invalid, then the invocation, and every consecutive call to the same function, results in a [trap](#).

Note

This is to allow implementations to use interpretation or just-in-time compilation for functions. The function must still be fully validated before execution of its body begins.

7.3.3 Execution

Restrictions on the following dimensions may be imposed during [execution](#) of a WebAssembly program:

- the number of allocated [module instances](#)
- the number of allocated [function instances](#)
- the number of allocated [table instances](#)
- the number of allocated [memory instances](#)
- the number of allocated [global instances](#)
- the number of allocated [tag instances](#)
- the number of allocated [structure instances](#)
- the number of allocated [array instances](#)
- the number of allocated [exception instances](#)
- the size of a [table instance](#)
- the size of a [memory instance](#)
- the size of an [array instance](#)
- the number of [frames](#) on the [stack](#)
- the number of [labels](#) on the [stack](#)
- the number of [values](#) on the [stack](#)

If the runtime limits of an implementation are exceeded during execution of a computation, then it may terminate that computation and report an embedder-specific error to the invoking code.

Some of the above limits may already be verified during instantiation, in which case an implementation may report exceedance in the same manner as for [syntactic limits](#).

Note

Concrete limits are usually not fixed but may be dependent on specifics, interdependent, vary over time, or depend on other implementation- or embedder-specific situations or events.

7.4 Type Soundness

The [type system](#) of WebAssembly is *sound*, implying both *type safety* and *memory safety* with respect to the WebAssembly semantics. For example:

- All types declared and derived during validation are respected at run time; e.g., every [local](#) or [global](#) variable will only contain type-correct values, every [instruction](#) will only be applied to operands of the expected type, and every [function invocation](#) always evaluates to a result of the right type (if it does not diverge, throw an exception, or [trap](#)).
- No memory location will be read or written except those explicitly defined by the program, i.e., as a [local](#), a [global](#), an element in a [table](#), or a location within a linear [memory](#).
- There is no undefined behavior, i.e., the [execution rules](#) cover all possible cases that can occur in a [valid](#) program, and the rules are mutually consistent.

Soundness also is instrumental in ensuring additional properties, most notably, *encapsulation* of function and module scopes: no [locals](#) can be accessed outside their own function and no [module](#) components can be accessed outside their own module unless they are explicitly [exported](#) or [imported](#).

The typing rules defining WebAssembly [validation](#) only cover the *static* components of a WebAssembly program. In order to state and prove soundness precisely, the typing rules must be extended to the *dynamic* components of the abstract [runtime](#), that is, the [store](#), [configurations](#), and [administrative instructions](#).⁵⁰

7.4.1 Contexts

In order to check [rolled up](#) recursive types, the [context](#) is locally extended with an additional component that records the [sub type](#) corresponding to each [recursive type index](#) within the current [recursive type](#):

$$C ::= \{ \dots, \text{recs } subtype^* \}$$

7.4.2 Types

Well-formedness for [extended type forms](#) is defined as follows.

Heap Type bot

- The heap type is valid.

$$\overline{C \vdash \text{bot} : \text{ok}}$$

⁵⁰ The formalization and theorems are derived from the following article: Andreas Haas, Andreas Rossberg, Derek Schuff, Ben Titzer, Dan Gohman, Luke Wagner, Alon Zakai, JF Bastien, Michael Holman. [Bringing the Web up to Speed with WebAssembly](#)⁵¹. Proceedings of the 38th ACM SIGPLAN Conference on Programming Language Design and Implementation (PLDI 2017). ACM 2017.

⁵¹ <https://dl.acm.org/citation.cfm?doid=3062341.3062363>

Heap Type $\text{rec } i$

- The recursive type index i must exist in $C.\text{recs}$.
- Then the heap type is valid.

$$\frac{C.\text{recs}[i] = \text{subtype}}{C \vdash \text{rec } i : \text{ok}}$$

Value Type bot

- The value type is valid.

$$\overline{C \vdash \text{bot} : \text{ok}}$$

Recursive Types rec subtype^*

- Let C' be the current context C , but where recs is subtype^* .
- There must be a type index x , such that for each sub type subtype_i in subtype^* :
 - Under the context C' , the sub type subtype_i must be valid for type index $x + i$ and recursive type index i .
- Then the recursive type is valid for the type index x .

$$\frac{C, \text{recs } \text{subtype}^* \vdash \text{rec } \text{subtype}^* : \text{ok}(x, 0)}{C \vdash \text{rec } \text{subtype}^* : \text{ok}(x)}$$

$$\frac{C \vdash \text{subtype} : \text{ok}(x, i) \quad C \vdash \text{rec } \text{subtype}'^* : \text{ok}(x + 1, i + 1)}{C \vdash \text{rec } \text{subtype } \text{subtype}'^* : \text{ok}(x, i)}$$

Note

These rules are a generalisation of the ones previously given.

Sub types $\text{sub final}^? \text{ ht}^* \text{ comptime}$

- The composite type comptime must be valid.
- The sequence ht^* may be no longer than 1.
- For every heap type ht_k in ht^* :
 - The heap type ht_k must be ordered before a type index x and recursive type index i , meaning:
 - * Either ht_k is a defined type.
 - * Or ht_k is a type index y_k that is smaller than x .
 - * Or ht_k is a recursive type index $\text{rec } j_k$ where j_k is smaller than i .
 - Let sub type subtype_k be the unrolling of the heap type ht_k , meaning:
 - * Either ht_k is a defined type deftype_k , then subtype_k must be the unrolling of deftype_k .
 - * Or ht_k is a type index y_k , then subtype_k must be the unrolling of the defined type $C.\text{types}[y_k]$.
 - * Or ht_k is a recursive type index $\text{rec } j_k$, then subtype_k must be $C.\text{recs}[j_k]$.
 - The sub type subtype_k must not contain **final**.
 - Let $\text{comptime}'_k$ be the composite type in subtype_k .
 - The composite type comptime must match $\text{comptime}'_k$.
- Then the sub type is valid for the type index x and recursive type index i .

$$\frac{\begin{array}{l} |ht^*| \leq 1 \quad (ht \prec x, i)^* \quad (\text{unroll}_C(ht) = \text{sub } ht'^* \text{ comptime}')^* \\ C \vdash \text{comptime} : \text{ok} \quad (C \vdash \text{comptime} \leq \text{comptime}')^* \end{array}}{C \vdash \text{sub final? } ht^* \text{ comptime} : \text{ok}(x, i)}$$

where:

$$\begin{aligned} (\text{deftype} \prec x, i) &= \text{true} \\ (y \prec x, i) &= y < x \\ (\text{rec } j \prec x, i) &= j < i \\ \text{unroll}_C(\text{deftype}) &= \text{unroll}(\text{deftype}) \\ \text{unroll}_C(y) &= \text{unroll}(C.\text{types}[y]) \\ \text{unroll}_C(\text{rec } j) &= C.\text{recs}[j] \end{aligned}$$

Note

This rule is a generalisation of the ones [previously given](#), which only allowed type indices as supertypes.

Defined types $\text{rectype}.i$

The defined type $(\text{rectype}.i)$ is valid if:

- The recursive type rectype is valid for the type index x .
- The recursive type rectype is of the form (rec subtype^n) .
- i is less than n .

$$\frac{C \vdash \text{rectype} : \text{ok}(x) \quad \text{rectype} = \text{rec subtype}^n \quad i < n}{C \vdash \text{rectype}.i : \text{ok}}$$

7.4.3 Subtyping

In a rolled-up recursive type, a recursive type indices $\text{rec } i$ matches another heap type ht if:

- Let $\text{sub final? } ht'^* \text{ comptime}$ be the sub type $C.\text{recs}[i]$.
- The heap type ht is contained in ht'^* .

$$\frac{C.\text{recs}[i] = \text{sub final? } (ht_1^* ht ht_2^*) \text{ comptime}}{C \vdash \text{rec } i \leq ht}$$

Note

This rule is only invoked when checking [validity](#) of rolled-up recursive types.

7.4.4 Results

Results can be classified by [result types](#) as follows.

Results val^*

- For each value val_i in val^* :
 - The value val_i is [valid](#) with some [value type](#) t_i .
- Let t^* be the concatenation of all t_i .
- Then the result is valid with [result type](#) $[t^*]$.

$$\frac{(S \vdash \text{val} : t)^*}{S \vdash \text{val}^* : [t^*]}$$

Results (ref.exn a) throw_ref

- The value ref.exn a must be valid.
- Then the result is valid with result type $[t^*]$, for any valid closed result types.

$$\frac{S \vdash \text{ref.exn } a : \text{ref exn} \quad \vdash [t^*] : \text{ok}}{S \vdash (\text{ref.exn } a) \text{ throw_ref} : [t^*]}$$

Results trap

- The result is valid with result type $[t^*]$, for any valid closed result types.

$$\frac{\vdash [t^*] : \text{ok}}{S \vdash \text{trap} : [t^*]}$$

7.4.5 Store Validity

The following typing rules specify when a runtime store S is *valid*. A valid store must consist of **tag**, **global**, **memory**, **table**, **function**, **data**, **element**, **structure**, **array**, **exception**, and **module** instances that are themselves valid, relative to S .

To that end, each kind of instance is classified by a respective **tag**, **global**, **memory**, **table**, **function**, or **element** type, or just **ok** in the case of **data structures**, **arrays**, or **exceptions**. Module instances are classified by *module contexts*, which are regular **contexts** repurposed as module types describing the **index spaces** defined by a module.

Store S

- Each tag instance taginst_i in $S.\text{tags}$ must be valid with some tag type tagtype_i .
- Each global instance globalinst_i in $S.\text{globals}$ must be valid with some global type globaltype_i .
- Each memory instance meminst_i in $S.\text{mems}$ must be valid with some memory type memtype_i .
- Each table instance tableinst_i in $S.\text{tables}$ must be valid with some table type tabletype_i .
- Each function instance funcinst_i in $S.\text{funcs}$ must be valid with some defined type deftype_i .
- Each data instance datainst_i in $S.\text{datas}$ must be valid.
- Each element instance eleminst_i in $S.\text{elems}$ must be valid with some reference type reftype_i .
- Each structure instance structinst_i in $S.\text{structs}$ must be valid.
- Each array instance arrayinst_i in $S.\text{arrays}$ must be valid.
- Each exception instance exninst_i in $S.\text{exns}$ must be valid.
- No **reference** to a bound **structure address** must be reachable from itself through a path consisting only of indirections through immutable structure, or array **fields** or fields of **exception instances**.
- No **reference** to a bound **array address** must be reachable from itself through a path consisting only of indirections through immutable structure or array **fields** or fields of **exception instances**.
- No **reference** to a bound **exception address** must be reachable from itself through a path consisting only of indirections through immutable structure or array **fields** or fields of **exception instances**.
- Then the store is valid.

$$\begin{array}{c}
(S \vdash \text{taginst} : \text{tagtype})^* \quad (S \vdash \text{globalinst} : \text{globaltype})^* \\
(S \vdash \text{meminst} : \text{memtype})^* \quad (S \vdash \text{tableinst} : \text{tabletype})^* \\
(S \vdash \text{funcinst} : \text{deftype})^* \quad (S \vdash \text{datainst} : \text{ok})^* \quad (S \vdash \text{eleminst} : \text{reftype})^* \\
(S \vdash \text{structinst} : \text{ok})^* \quad (S \vdash \text{arrayinst} : \text{ok})^* \quad (S \vdash \text{exninst} : \text{ok})^* \\
S = \{\text{tags } \text{taginst}^*, \text{globals } \text{globalinst}^*, \text{mems } \text{meminst}^*, \text{tables } \text{tableinst}^*, \text{funcs } \text{funcinst}^*, \\
\text{datas } \text{datainst}^*, \text{elems } \text{eleminst}^*, \text{structs } \text{structinst}^*, \text{arrays } \text{arrayinst}^*, \text{exns } \text{exninst}^*\} \\
\frac{
\begin{array}{c}
(S.\text{structs}[a_s] = \text{structinst})^* \quad ((\text{ref.struct } a_s) \gg_S^+ (\text{ref.struct } a_s))^* \\
(S.\text{arrays}[a_a] = \text{arrayinst})^* \quad ((\text{ref.array } a_a) \gg_S^+ (\text{ref.array } a_a))^* \\
(S.\text{exns}[a_e] = \text{exninst})^* \quad ((\text{ref.exn } a_e) \gg_S^+ (\text{ref.exn } a_e))^*
\end{array}
}{\vdash S : \text{ok}}
\end{array}$$

where $\text{val}_1 \gg_S^+ \text{val}_2$ denotes the transitive closure of the following *immutable reachability* relation on *values*:

$$\begin{array}{ll}
(\text{ref.struct } a) & \gg_S S.\text{structs}[a].\text{fields}[i] \quad \text{if } \text{expand}(S.\text{structs}[a].\text{type}) = \text{struct } ft_1^i \text{ st } ft_2^* \\
(\text{ref.array } a) & \gg_S S.\text{arrays}[a].\text{fields}[i] \quad \text{if } \text{expand}(S.\text{arrays}[a].\text{type}) = \text{array } st \\
(\text{ref.exn } a) & \gg_S S.\text{exns}[a].\text{fields}[i] \\
(\text{ref.extern } ref) & \gg_S ref
\end{array}$$

Note

The constraint on reachability through immutable fields prevents the presence of cyclic data structures that can not be constructed in the language. Cycles can only be formed using mutation.

Tag Instances $\{\text{type } \text{tagtype}\}$

- The tag type *tagtype* must be valid under the empty context.
- Then the tag instance is valid with tag type *tagtype*.

$$\frac{\vdash \text{tagtype} : \text{ok}}{S \vdash \{\text{type } \text{tagtype}\} : \text{tagtype}}$$

Global Instances $\{\text{type } \text{mut } t, \text{value } \text{val}\}$

- The global type *mut t* must be valid under the empty context.
- The value *val* must be valid with some value type *t'*.
- The value type *t'* must match the value type *t*.
- Then the global instance is valid with global type *mut t*.

$$\frac{\vdash \text{mut } t : \text{ok} \quad S \vdash \text{val} : t' \quad \vdash t' \leq t}{S \vdash \{\text{type } \text{mut } t, \text{value } \text{val}\} : \text{mut } t}$$

Memory Instances $\{\text{type } (\text{addrtype } \text{limits}), \text{bytes } b^*\}$

- The memory type *addrtype limits* must be valid under the empty context.
- Let *limits* be $[n .. m]$.
- The length of *b** must equal *m* multiplied by the page size 64 Ki.
- Then the memory instance is valid with memory type *addrtype limits*.

$$\frac{\vdash \text{addrtype } [n .. m] : \text{ok} \quad |b^*| = n \cdot 64 \text{ Ki}}{S \vdash \{\text{type } (\text{addrtype } [n .. m]), \text{bytes } b^*\} : \text{addrtype } [n .. m]}$$

Table Instances $\{\text{type } (\text{addrtype limits } t), \text{elem } \text{ref}^*\}$

- The table type *addrtype limits t* must be valid under the empty context.
- Let *limits* be $[n .. m]$.
- The length of *ref*^{*} must equal *n*.
- For each reference *ref*_{*i*} in the table's elements *ref*ⁿ:
 - The reference *ref*_{*i*} must be valid with some reference type *t*'_{*i*}.
 - The reference type *t*'_{*i*} must match the reference type *t*.
- Then the table instance is valid with table type *addrtype limits t*.

$$\frac{\vdash \text{addrtype } [n .. m] \ t : \text{ok} \quad |\text{ref}^*| = n \quad (S \vdash \text{ref} : t')^* \quad (\vdash t' \leq t)^*}{S \vdash \{\text{type } (\text{addrtype } [n .. m] \ t), \text{elem } \text{ref}^*\} : \text{addrtype } [n .. m] \ t}$$

Function Instances $\{\text{type } \text{deftype}, \text{module } \text{moduleinst}, \text{code } \text{func}\}$

- The defined type *deftype* must be valid under an empty context.
- The module instance *moduleinst* must be valid with some context *C*.
- Under context *C*:
 - The function *func* must be valid with some defined type *deftype*'.
 - The defined type *deftype*' must match *deftype*.
- Then the function instance is valid with defined type *deftype*.

$$\frac{\vdash \text{deftype} : \text{ok} \quad S \vdash \text{moduleinst} : C \quad C \vdash \text{func} : \text{deftype}' \quad C \vdash \text{deftype}' \leq \text{deftype}}{S \vdash \{\text{type } \text{deftype}, \text{module } \text{moduleinst}, \text{code } \text{func}\} : \text{deftype}}$$

Host Function Instances $\{\text{type } \text{deftype}, \text{hostfunc } \text{hf}\}$

- The defined type *deftype* must be valid under an empty context.
- The expansion of defined type *deftype* must be some function type $\text{func } [t_1^*] \rightarrow [t_2^*]$.
- For every valid store *S*₁ extending *S* and every sequence *val*^{*} of values whose types coincide with *t*₁^{*}:
 - Executing *hf* in store *S*₁ with arguments *val*^{*} has a non-empty set of possible outcomes.
 - For every element *R* of this set:
 - * Either *R* must be \perp (i.e., divergence).
 - * Or *R* consists of a valid store *S*₂ extending *S*₁ and a result *result* whose type coincides with *t*₂^{*}.
- Then the function instance is valid with defined type *deftype*.

$$\frac{\begin{array}{l} \forall S_1, \text{val}^*, \vdash S_1 : \text{ok} \wedge \vdash S \preceq S_1 \wedge S_1 \vdash \text{val}^* : [t_1^*] \implies \\ \quad \text{hf}(S_1; \text{val}^*) \supset \emptyset \wedge \\ \vdash \text{deftype} : \text{ok} \quad \forall R \in \text{hf}(S_1; \text{val}^*), R = \perp \vee \\ \text{deftype} \approx \text{func } [t_1^*] \rightarrow [t_2^*] \quad \exists S_2, \text{result}, \vdash S_2 : \text{ok} \wedge \vdash S_1 \preceq S_2 \wedge S_2 \vdash \text{result} : [t_2^*] \wedge R = (S_2; \text{result}) \end{array}}{S \vdash \{\text{type } \text{deftype}, \text{hostfunc } \text{hf}\} : \text{deftype}}$$

Note

This rule states that, if appropriate pre-conditions about store and arguments are satisfied, then executing the host function must satisfy appropriate post-conditions about store and results. The post-conditions match the ones in the [execution rule](#) for invoking host functions.

Any store under which the function is invoked is assumed to be an extension of the current store. That way, the function itself is able to make sufficient assumptions about future stores.

Data Instances $\{\text{bytes } b^*\}$

- The data instance is valid.

$$\overline{S \vdash \{\text{bytes } b^*\} : \text{ok}}$$

Element Instances $\{\text{type } t, \text{elem } \text{ref}^*\}$

- The reference type t must be valid under the empty context.
- For each reference ref_i in the elements ref^n :
 - The reference ref_i must be valid with some reference type t'_i .
 - The reference type t'_i must match the reference type t .
- Then the element instance is valid with reference type t .

$$\frac{\vdash t : \text{ok} \quad (S \vdash \text{ref} : t')^* \quad (\vdash t' \leq t)^*}{S \vdash \{\text{type } t, \text{elem } \text{ref}^*\} : t}$$

Structure Instances $\{\text{type } \text{deftype}, \text{fields } \text{fieldval}^*\}$

- The defined type deftype must be valid under the empty context.
- The expansion of deftype must be a structure type $\text{struct } \text{fieldtype}^*$.
- The length of the sequence of field values fieldval^* must be the same as the length of the sequence of field types fieldtype^* .
- For each field value fieldval_i in fieldval^* and corresponding field type fieldtype_i in fieldtype^* :
 - Let fieldtype_i be $\text{mut } \text{storagetype}_i$.
 - The field value fieldval_i must be valid with storage type storagetype_i .
- Then the structure instance is valid.

$$\frac{\vdash dt : \text{ok} \quad \text{expand}(dt) = \text{struct } (\text{mut } st)^* \quad (S \vdash fv : st)^*}{S \vdash \{\text{type } dt, \text{fields } fv^*\} : \text{ok}}$$

Array Instances $\{\text{type } \text{deftype}, \text{fields } \text{fieldval}^*\}$

- The defined type deftype must be valid under the empty context.
- The expansion of deftype must be an array type $\text{array } \text{fieldtype}$.
- Let fieldtype be $\text{mut } \text{storagetype}$.
- For each field value fieldval_i in fieldval^* :
 - The field value fieldval_i must be valid with storage type storagetype .
- Then the array instance is valid.

$$\frac{\vdash dt : \text{ok} \quad \text{expand}(dt) = \text{array } (\text{mut } st) \quad (S \vdash fv : st)^*}{S \vdash \{\text{type } dt, \text{fields } fv^*\} : \text{ok}}$$

Field Values *fieldval*

- If *fieldval* is a value *val*, then:
 - The value *val* must be valid with value type *t*.
 - Then the field value is valid with value type *t*.
- Else, *fieldval* is a packed value *packval*:
 - Let *packtype.pack i* be the field value *fieldval*.
 - Then the field value is valid with packed type *packtype*.

$$\frac{}{S \vdash pt.pack\ i : pt}$$

Exception Instances {tag *a*, fields *val*^{*}}

- The store entry *S.tags[a]* must exist.
- The expansion of the tag type *S.tags[a].type* must be some function type *func [t^{*}] → [t'^{*}]*.
- The result type *[t'^{*}]* must be empty.
- The sequence *val^ast* of values must have the same length as the sequence *t^{*}* of value types.
- For each value *val_i* in *val^ast* and corresponding value type *t_i* in *t^{*}*, the value *val_i* must be valid with type *t_i*.
- Then the exception instance is valid.

$$\frac{S.tags[a].type \approx func\ [t^*] \rightarrow [] \quad (S \vdash val : t)^*}{S \vdash \{tag\ a, fields\ val^*\} : ok}$$

Export Instances {name *name*, addr *externaddr*}

- The external address *externaddr* must be valid with some external type *externtype*.
- Then the export instance is valid.

$$\frac{S \vdash externaddr : externtype}{S \vdash \{name\ name, addr\ externaddr\} : ok}$$

Module Instances *moduleinst*

- Each defined type *deftype_i* in *moduleinst.types* must be valid under the empty context.
- For each tag address *tagaddr_i* in *moduleinst.tags*, the external address tag *tagaddr_i* must be valid with some external type tag *tagtype_i*.
- For each global address *globaladdr_i* in *moduleinst.globals*, the external address global *globaladdr_i* must be valid with some external type global *globaltype_i*.
- For each memory address *memaddr_i* in *moduleinst.mems*, the external address mem *memaddr_i* must be valid with some external type mem *memtype_i*.
- For each table address *tableaddr_i* in *moduleinst.tables*, the external address table *tableaddr_i* must be valid with some external type table *tabletype_i*.
- For each function address *funcaddr_i* in *moduleinst.funcs*, the external address func *funcaddr_i* must be valid with some external type func *deftype_{F_i}*.
- For each data address *dataaddr_i* in *moduleinst.datas*, the data instance *S.datas[dataaddr_i]* must be valid with *ok_i*.

- For each element address $elemaddr_i$ in $moduleinst.elems$, the element instance $S.elems[elemaddr_i]$ must be valid with some reference type $reftype_i$.
- Each export instance $exportinst_i$ in $moduleinst.exports$ must be valid.
- For each export instance $exportinst_i$ in $moduleinst.exports$, the name $exportinst_i.name$ must be different from any other name occurring in $moduleinst.exports$.
- Let $deftype^*$ be the concatenation of all $deftype_i$ in order.
- Let $tagtype^*$ be the concatenation of all $tagtype_i$ in order.
- Let $globaltype^*$ be the concatenation of all $globaltype_i$ in order.
- Let $memtype^*$ be the concatenation of all $memtype_i$ in order.
- Let $tabletype^*$ be the concatenation of all $tabletype_i$ in order.
- Let $deftype_F^*$ be the concatenation of all $deftype_{F_i}$ in order.
- Let $reftype^*$ be the concatenation of all $reftype_i$ in order.
- Let ok^* be the concatenation of all ok_i in order.
- Let m be the length of $moduleinst.funcs$.
- Let x^* be the sequence of function indices from 0 to $m - 1$.
- Then the module instance is valid with context $\{\text{types } deftype^*, \text{tags } tagtype^*, \text{globals } globaltype^*, \text{mems } memtype^*, \text{tables } tabletype^*, \text{funcs } deftype_F^*, \text{datas } ok^*, \text{elems } reftype^*, \text{refs } x^*\}$.

$$\begin{array}{c}
\begin{array}{cc}
(\vdash deftype : ok)^* & (S \vdash \text{tag } tagaddr : \text{tag } tagtype)^* \\
(S \vdash \text{global } globaladdr : \text{global } globaltype)^* & (S \vdash \text{func } funcaddr : \text{func } deftype_F)^* \\
(S \vdash \text{mem } memaddr : \text{mem } memtype)^* & (S \vdash \text{table } tableaddr : \text{table } tabletype)^* \\
(S \vdash S.datas[dataaddr] : ok)^* & (S \vdash S.elems[elemaddr] : reftype)^* \\
(S \vdash exportinst : ok)^* & (exportinst.name)^* \text{ disjoint}
\end{array} \\
\hline
S \vdash \{ \text{types } deftype^*, \\
\text{tags } tagaddr^*, \\
\text{globals } globaladdr^*, \\
\text{mems } memaddr^*, \\
\text{tables } tableaddr^*, \\
\text{funcs } funcaddr^*, \\
\text{datas } dataaddr^*, \\
\text{elems } elemaddr^*, \\
\text{exports } exportinst^* \} : \{ \text{types } deftype^*, \\
\text{tags } tagtype^*, \\
\text{globals } globaltype^*, \\
\text{mems } memtype^*, \\
\text{tables } tabletype^*, \\
\text{funcs } deftype_F^*, \\
\text{datas } ok^*, \\
\text{elems } reftype^*, \\
\text{refs } 0 \dots (|funcaddr^*| - 1) \}
\end{array}$$

7.4.6 Configuration Validity

To relate the WebAssembly type system to its execution semantics, the typing rules for instructions must be extended to configurations $S; T$, which relates the store to execution threads.

Configurations and threads are classified by their result type. In addition to the store S , threads are typed under a return type $resulttype^?$, which controls whether and with which type a `return` instruction is allowed. This type is absent (ϵ) except for instruction sequences inside an administrative `frame` instruction.

Finally, **frames** are classified with *frame contexts*, which extend the **module contexts** of a frame's associated **module instance** with the **locals** that the frame contains.

Configurations $S; T$

- The **store** S must be **valid**.
- Under no allowed return type, the **thread** T must be **valid** with some **result type** $[t^*]$.
- Then the configuration is valid with the **result type** $[t^*]$.

$$\frac{\vdash S : \text{ok} \quad S; \epsilon \vdash T : [t^*]}{\vdash S; T : [t^*]}$$

Threads $F; instr^*$

- Let *resulttype*[?] be the current allowed return type.
- The **frame** F must be **valid** with a **context** C .
- Let C' be the same **context** as C , but with **return** set to *resulttype*[?].
- Under context C' , the instruction sequence $instr^*$ must be **valid** with some type $\square \rightarrow [t^*]$.
- Then the thread is valid with the **result type** $[t^*]$.

$$\frac{S \vdash F : C \quad S; C, \text{return } resulttype^? \vdash instr^* : \square \rightarrow [t^*]}{S; resulttype^? \vdash F; instr^* : [t^*]}$$

Frames $\{\text{locals } val^*, \text{module } moduleinst\}$

- The **module instance** $moduleinst$ must be **valid** with some **module context** C .
- Each **value** val_i in val^* must be **valid** with some **value type** t_i .
- Let t^* be the concatenation of all t_i in order.
- Let C' be the same **context** as C , but with the **value types** t^* prepended to the **locals** list.
- Then the frame is valid with **frame context** C' .

$$\frac{S \vdash moduleinst : C \quad (S \vdash val : t)^*}{S \vdash \{\text{locals } val^*, \text{module } moduleinst\} : (C, \text{locals } t^*)}$$

7.4.7 Administrative Instructions

Typing rules for **administrative instructions** are specified as follows. In addition to the **context** C , typing of these instructions is defined under a given **store** S .

To that end, all previous typing judgements $C \vdash prop$ are generalized to include the store, as in $S; C \vdash prop$, by implicitly adding S to all rules – S is never modified by the pre-existing rules, but it is accessed in the extra rules for **administrative instructions** given below.

trap

- The instruction is valid with any **valid instruction type** of the form $[t_1^*] \rightarrow [t_2^*]$.

$$\frac{C \vdash [t_1^*] \rightarrow [t_2^*] : \text{ok}}{S; C \vdash \text{trap} : [t_1^*] \rightarrow [t_2^*]}$$

val

- The value *val* must be valid with value type *t*.
- Then it is valid as an instruction with type $\square \rightarrow [t]$.

$$\frac{S \vdash \text{val} : t}{S; C \vdash \text{val} : \square \rightarrow [t]}$$

invoke *funcaddr*

- The external function address *func funcaddr* must be valid with external function type *func deftype'*.
- The expansion of the defined type *deftype* must be some function type *func* $[t_1^*] \rightarrow [t_2^*]$.
- Then the instruction is valid with type $[t_1^*] \rightarrow [t_2^*]$.

$$\frac{S \vdash \text{func funcaddr} : \text{func deftype} \quad \text{deftype} \approx \text{func } [t_1^*] \rightarrow [t_2^*]}{S; C \vdash \text{invoke funcaddr} : [t_1^*] \rightarrow [t_2^*]}$$

label_{*n*}{*instr*₀^{*}} *instr*^{*}

- The instruction sequence *instr*₀^{*} must be valid with some type $[t_1^n] \rightarrow_{x^*} [t_2^*]$.
- Let *C'* be the same context as *C*, but with the result type $[t_1^n]$ prepended to the labels list.
- Under context *C'*, the instruction sequence *instr*^{*} must be valid with type $\square \rightarrow_{x'^*} [t_2^*]$.
- Then the compound instruction is valid with type $\square \rightarrow [t_2^*]$.

$$\frac{S; C \vdash \text{instr}_0^* : [t_1^n] \rightarrow_{x^*} [t_2^*] \quad S; C, \text{labels } [t_1^n] \vdash \text{instr}^* : \square \rightarrow_{x'^*} [t_2^*]}{S; C \vdash \text{label}_n\{\text{instr}_0^*\} \text{ instr}^* : \square \rightarrow [t_2^*]}$$

frame_{*n*}{*F*} *instr*^{*}

- Under the valid return type $[t^n]$, the thread *F*; *instr*^{*} must be valid with result type $[t^n]$.
- Then the compound instruction is valid with type $\square \rightarrow [t^n]$.

$$\frac{C \vdash [t^n] : \text{ok} \quad S; [t^n] \vdash F; \text{instr}^* : [t^n]}{S; C \vdash \text{frame}_n\{F\} \text{ instr}^* : \square \rightarrow [t^n]}$$

handler_{*n*}{*catch*^{*}} *instr*^{*}

- For every catch clause *catch*_{*i*} in *catch*^{*}, *catch*_{*i*} must be valid.
- The instruction sequence *instr*^{*} must be valid with some type $[t_1^*] \rightarrow [t_2^*]$.
- Then the compound instruction is valid with type $[t_1^*] \rightarrow [t_2^*]$.

$$\frac{(C \vdash \text{catch} : \text{ok})^* \quad S; C \vdash \text{instr}^* : [t_1^*] \rightarrow [t_2^*]}{S; C \vdash \text{handler}_n\{\text{catch}^*\} \text{ instr}^* : [t_1^*] \rightarrow [t_2^*]}$$

7.4.8 Store Extension

Programs can mutate the store and its contained instances. Any such modification must respect certain invariants, such as not removing allocated instances or changing immutable definitions. While these invariants are inherent to the execution semantics of WebAssembly instructions and modules, host functions do not automatically adhere to them. Consequently, the required invariants must be stated as explicit constraints on the invocation of host functions. Soundness only holds when the embedder ensures these constraints.

The necessary constraints are codified by the notion of store *extension*: a store state S' extends state S , written $S \preceq S'$, when the following rules hold.

Note

Extension does not imply that the new store is valid, which is defined separately [above](#).

Store S

- The length of $S.\text{tags}$ must not shrink.
- The length of $S.\text{globals}$ must not shrink.
- The length of $S.\text{mems}$ must not shrink.
- The length of $S.\text{tables}$ must not shrink.
- The length of $S.\text{funcs}$ must not shrink.
- The length of $S.\text{datas}$ must not shrink.
- The length of $S.\text{elems}$ must not shrink.
- The length of $S.\text{structs}$ must not shrink.
- The length of $S.\text{arrays}$ must not shrink.
- The length of $S.\text{exns}$ must not shrink.
- For each tag instance taginst_i in the original $S.\text{tags}$, the new tag instance must be an [extension](#) of the old.
- For each global instance globalinst_i in the original $S.\text{globals}$, the new global instance must be an [extension](#) of the old.
- For each memory instance meminst_i in the original $S.\text{mems}$, the new memory instance must be an [extension](#) of the old.
- For each table instance tableinst_i in the original $S.\text{tables}$, the new table instance must be an [extension](#) of the old.
- For each function instance funcinst_i in the original $S.\text{funcs}$, the new function instance must be an [extension](#) of the old.
- For each data instance datainst_i in the original $S.\text{datas}$, the new data instance must be an [extension](#) of the old.
- For each element instance eleminst_i in the original $S.\text{elems}$, the new element instance must be an [extension](#) of the old.
- For each structure instance structinst_i in the original $S.\text{structs}$, the new structure instance must be an [extension](#) of the old.
- For each array instance arrayinst_i in the original $S.\text{arrays}$, the new array instance must be an [extension](#) of the old.
- For each exception instance exninst_i in the original $S.\text{exns}$, the new exception instance must be an [extension](#) of the old.

$$\begin{array}{lll}
S_1.\text{tags} = \text{taginst}_1^* & S_2.\text{tags} = \text{taginst}'_1^* \text{taginst}_2^* & (\vdash \text{taginst}_1 \preceq \text{taginst}'_1)^* \\

\end{array}$$

$$\vdash S_1 \preceq S_2$$

Tag Instance *taginst*

- A tag instance must remain unchanged.

$$\vdash \text{taginst} \preceq \text{taginst}$$

Global Instance *globalinst*

- The global type *globalinst.type* must remain unchanged.
- Let *mut t* be the structure of *globalinst.type*.
- If *mut* is empty, then the value *globalinst.value* must remain unchanged.

$$\frac{\text{mut} = \text{mut} \vee \text{val}_1 = \text{val}_2}{\vdash \{\text{type}(\text{mut } t), \text{value } \text{val}_1\} \preceq \{\text{type}(\text{mut } t), \text{value } \text{val}_2\}}$$

Memory Instance *meminst*

- The memory type *meminst.type* must remain unchanged.
- The length of *meminst.bytes* must not shrink.

$$\frac{n_1 \leq n_2}{\vdash \{\text{type } mt, \text{bytes } b_1^{n_1}\} \preceq \{\text{type } mt, \text{bytes } b_2^{n_2}\}}$$

Table Instance *tableinst*

- The table type *tableinst.type* must remain unchanged.
- The length of *tableinst.elem* must not shrink.

$$\frac{n_1 \leq n_2}{\vdash \{\text{type } tt, \text{elem } (fa_1^{n_1})\} \preceq \{\text{type } tt, \text{elem } (fa_2^{n_2})\}}$$

Function Instance *funcinst*

- A function instance must remain unchanged.

$$\vdash \text{funcinst} \preceq \text{funcinst}$$

Data Instance *datainst*

- The list *datainst.bytes* must:
 - either remain unchanged,
 - or shrink to length 0.

$$\frac{}{\vdash \{\text{bytes } b^*\} \preceq \{\text{bytes } b^*\}}$$

$$\frac{}{\vdash \{\text{bytes } b^*\} \preceq \{\text{bytes } \epsilon\}}$$

Element Instance *eleminst*

- The reference type *eleminst.type* must remain unchanged.
- The list *eleminst.elem* must:
 - either remain unchanged,
 - or shrink to length 0.

$$\frac{}{\vdash \{\text{type } t, \text{elem } a^*\} \preceq \{\text{type } t, \text{elem } a^*\}}$$

$$\frac{}{\vdash \{\text{type } t, \text{elem } a^*\} \preceq \{\text{type } t, \text{elem } \epsilon\}}$$

Structure Instance *structinst*

- The defined type *structinst.type* must remain unchanged.
- Assert: due to store well-formedness, the expansion of *structinst.type* is a structure type.
- Let struct *fieldtype** be the expansion of *structinst.type*.
- The length of the list *structinst.fields* must remain unchanged.
- Assert: due to store well-formedness, the length of *structinst.fields* is the same as the length of *fieldtype**.
- For each field value *fieldval_i* in *structinst.fields* and corresponding field type *fieldtype_i* in *fieldtype**:
 - Let *mut_i st_i* be the structure of *fieldtype_i*.
 - If *mut_i* is empty, then the field value *fieldval_i* must remain unchanged.

$$\frac{(mut = mut \vee fieldval_1 = fieldval_2)^*}{\vdash \{\text{type } (mut \text{ st})^*, \text{fields } fieldval_1^*\} \preceq \{\text{type } (mut \text{ st})^*, \text{fields } fieldval_2^*\}}$$

Array Instance *arrayinst*

- The defined type *arrayinst.type* must remain unchanged.
- Assert: due to store well-formedness, the expansion of *arrayinst.type* is an array type.
- Let array *fieldtype* be the expansion of *arrayinst.type*.
- The length of the list *arrayinst.fields* must remain unchanged.
- Let *mut st* be the structure of *fieldtype*.
- If *mut* is empty, then the sequence of field values *arrayinst.fields* must remain unchanged.

$$\frac{mut = mut \vee fieldval_1^* = fieldval_2^*}{\vdash \{\text{type } (mut \text{ st}), \text{fields } fieldval_1^*\} \preceq \{\text{type } (mut \text{ st}), \text{fields } fieldval_2^*\}}$$

Exception Instance *exninst*

- An exception instance must remain unchanged.

$$\overline{\vdash \text{exninst} \preceq \text{exninst}}$$

7.4.9 Theorems

Given the definition of **valid configurations**, the standard soundness theorems hold.⁵²⁵⁴

Theorem (Preservation). If a **configuration** $S;T$ is **valid** with **result type** $[t^*]$ (i.e., $\vdash S;T : [t^*]$), and steps to $S';T'$ (i.e., $S;T \hookrightarrow S';T'$), then $S';T'$ is a valid configuration with the same result type (i.e., $\vdash S';T' : [t^*]$). Furthermore, S' is an **extension** of S (i.e., $\vdash S \preceq S'$).

A **terminal thread** is one whose sequence of **instructions** is a **result**. A terminal configuration is a configuration whose thread is terminal.

Theorem (Progress). If a **configuration** $S;T$ is **valid** (i.e., $\vdash S;T : [t^*]$ for some **result type** $[t^*]$), then either it is terminal, or it can step to some configuration $S';T'$ (i.e., $S;T \hookrightarrow S';T'$).

From Preservation and Progress the soundness of the WebAssembly type system follows directly.

Corollary (Soundness). If a **configuration** $S;T$ is **valid** (i.e., $\vdash S;T : [t^*]$ for some **result type** $[t^*]$), then it either diverges or takes a finite number of steps to reach a terminal configuration $S';T'$ (i.e., $S;T \hookrightarrow^* S';T'$) that is valid with the same result type (i.e., $\vdash S';T' : [t^*]$) and where S' is an **extension** of S (i.e., $\vdash S \preceq S'$).

In other words, every thread in a valid configuration either runs forever, traps, throws an exception, or terminates with a result that has the expected type. Consequently, given a **valid store**, no computation defined by **instantiation** or **invocation** of a valid module can “crash” or otherwise (mis)behave in ways not covered by the **execution** semantics given in this specification.

7.5 Type System Properties**7.5.1 Principal Types**

The **type system** of WebAssembly features both **subtyping** and simple forms of **polymorphism** for **instruction types**. That has the effect that every instruction or instruction sequence can be classified with multiple different instruction types.

However, the typing rules still allow deriving *principal types* for instruction sequences. That is, every valid instruction sequence has one particular type scheme, possibly containing some unconstrained place holder *type variables*, that is a subtype of all its valid instruction types, after substituting its type variables with suitable specific types.

Moreover, when deriving an instruction type in a “forward” manner, i.e., the *input* of the instruction sequence is already fixed to specific types, then it has a principal *output* type expressible without type variables, up to a possibly **polymorphic stack** bottom representable with one single variable. In other words, “forward” principal types are effectively *closed*.

Note

For example, in isolation, the instruction `ref.as_non_null` has the type $[(\text{ref } \text{null } ht)] \rightarrow [(\text{ref } ht)]$ for any choice of valid **heap type** ht . Moreover, if the input type $[(\text{ref } \text{null } ht)]$ is already determined, i.e., a specific ht is given, then the output type $[(\text{ref } ht)]$ is fully determined as well.

⁵² A machine-verified version of the formalization and soundness proof of the PLDI 2017 paper is described in the following article: Conrad Watt. *Mechanising and Verifying the WebAssembly Specification*⁵³. Proceedings of the 7th ACM SIGPLAN Conference on Certified Programs and Proofs (CPP 2018). ACM 2018.

⁵³ <https://dl.acm.org/citation.cfm?id=3167082>

⁵⁴ Machine-verified formalizations and soundness proofs of the semantics from the official specification are described in the following article: Conrad Watt, Xiaojia Rao, Jean Pichon-Pharabod, Martin Bodin, Philippa Gardner. *Two Mechanisations of WebAssembly 1.0*⁵⁵. Proceedings of the 24th International Symposium on Formal Methods (FM 2021). Springer 2021.

⁵⁵ https://link.springer.com/chapter/10.1007/978-3-030-90870-6_4

The implication of the latter property is that a validator for *complete* instruction sequences (as they occur in valid modules) can be implemented with a simple left-to-right [algorithm](#) that does not require the introduction of type variables.

A typing algorithm capable of handling *partial* instruction sequences (as might be considered for program analysis or program manipulation) needs to introduce type variables and perform substitutions, but it does not need to perform backtracking or record any non-syntactic constraints on these type variables.

Technically, the [syntax](#) of [heap](#), [value](#), and [result](#) types can be enriched with type variables as follows:

$$\begin{aligned} \text{null} &::= \text{null}^? \mid \alpha_{\text{null}} \\ \text{heapttype} &::= \dots \mid \alpha_{\text{heapttype}} \\ \text{reftype} &::= \text{ref null heapttype} \\ \text{valtype} &::= \dots \mid \alpha_{\text{valtype}} \mid \alpha_{\text{numvectype}} \\ \text{resulttype} &::= [\alpha_{\text{valtype}}^? \text{ valtype}^*] \end{aligned}$$

where each α_{xyz} ranges over a set of type variables for syntactic class *xyz*, respectively. The special class *numvectype* is defined as *numtype* | *vectype* | *bot*, and is only needed to handle unannotated [select](#) instructions.

A type is *closed* when it does not contain any type variables, and *open* otherwise. A *type substitution* σ is a finite mapping from type variables to closed types of the respective syntactic class. When applied to an open type, it replaces the type variables α from its domain with the respective $\sigma(\alpha)$.

Theorem (Principal Types). If an instruction sequence instr^* is [valid](#) with some closed instruction type instrtype (i.e., $C \vdash \text{instr}^* : \text{instrtype}$), then it is also valid with a possibly open instruction type instrtype_{\min} (i.e., $C \vdash \text{instr}^* : \text{instrtype}_{\min}$), such that for *every* closed type $\text{instrtype}'$ with which instr^* is valid (i.e., for all $C \vdash \text{instr}^* : \text{instrtype}'$), there exists a substitution σ , such that $\sigma(\text{instrtype}_{\min})$ is a subtype of $\text{instrtype}'$ (i.e., $C \vdash \sigma(\text{instrtype}_{\min}) \leq \text{instrtype}'$). Furthermore, instrtype_{\min} is unique up to the choice of type variables.

Theorem (Closed Principal Forward Types). If closed input type $[t_1^*]$ is given and the instruction sequence instr^* is [valid](#) with instruction type $[t_1^*] \rightarrow_{x^*} [t_2^*]$ (i.e., $C \vdash \text{instr}^* : [t_1^*] \rightarrow_{x^*} [t_2^*]$), then it is also valid with instruction type $[t_1^*] \rightarrow_{x^*} [\alpha_{\text{valtype}}^* t^*]$ (i.e., $C \vdash \text{instr}^* : [t_1^*] \rightarrow_{x^*} [\alpha_{\text{valtype}}^* t^*]$), where all t^* are closed, such that for *every* closed result type $[t_2'^*]$ with which instr^* is valid (i.e., for all $C \vdash \text{instr}^* : [t_1^*] \rightarrow_{x^*} [t_2'^*]$), there exists a substitution σ , such that $[t_2'^*] = [\sigma(\alpha_{\text{valtype}}^*) t^*]$.

7.5.2 Type Lattice

The [Principal Types](#) property depends on the existence of a *greatest lower bound* for any pair of types.

Theorem (Greatest Lower Bounds for Value Types). For any two value types t_1 and t_2 that are [valid](#) (i.e., $C \vdash t_1 : \text{ok}$ and $C \vdash t_2 : \text{ok}$), there exists a valid value type t that is a subtype of both t_1 and t_2 (i.e., $C \vdash t : \text{ok}$ and $C \vdash t \leq t_1$ and $C \vdash t \leq t_2$), such that *every* valid value type t' that also is a subtype of both t_1 and t_2 (i.e., for all $C \vdash t' : \text{ok}$ and $C \vdash t' \leq t_1$ and $C \vdash t' \leq t_2$), is a subtype of t (i.e., $C \vdash t' \leq t$).

Note

The greatest lower bound of two types may be [bot](#).

Theorem (Conditional Least Upper Bounds for Value Types). Any two value types t_1 and t_2 that are [valid](#) (i.e., $C \vdash t_1 : \text{ok}$ and $C \vdash t_2 : \text{ok}$) either have no common supertype, or there exists a valid value type t that is a supertype of both t_1 and t_2 (i.e., $C \vdash t : \text{ok}$ and $C \vdash t_1 \leq t$ and $C \vdash t_2 \leq t$), such that *every* valid value type t' that also is a supertype of both t_1 and t_2 (i.e., for all $C \vdash t' : \text{ok}$ and $C \vdash t_1 \leq t'$ and $C \vdash t_2 \leq t'$), is a supertype of t (i.e., $C \vdash t \leq t'$).

Note

If a top type was added to the type system, a least upper bound would exist for any two types.

Corollary (Type Lattice). Assuming the addition of a provisional top type, **value types** form a lattice with respect to their **subtype** relation.

Finally, value types can be partitioned into multiple disjoint hierarchies that are not related by subtyping, except through **bot**.

Theorem (Disjoint Subtype Hierarchies). The greatest lower bound of two **value types** is **bot** or **ref bot** if and only if they do not have a least upper bound.

In other words, types that do not have common supertypes, do not have common subtypes either (other than **bot** or **ref bot**), and vice versa.

Note

Types from disjoint hierarchies can safely be represented in mutually incompatible ways in an implementation, because their values can never flow to the same place.

7.5.3 Compositionality

Valid instruction sequences can be freely *composed*, as long as their types match up.

Theorem (Composition). If two instruction sequences $instr_1^*$ and $instr_2^*$ are valid with types $[t_1^*] \rightarrow_{x_1^*} [t^*]$ and $[t^*] \rightarrow_{x_2^*} [t_2^*]$, respectively (i.e., $C \vdash instr_1^* : [t_1^*] \rightarrow_{x_1^*} [t^*]$ and $C \vdash instr_2^* : [t^*] \rightarrow_{x_2^*} [t_2^*]$), then the concatenated instruction sequence $(instr_1^* instr_2^*)$ is valid with type $[t_1^*] \rightarrow_{x_1^* x_2^*} [t_2^*]$ (i.e., $C \vdash instr_1^* instr_2^* : [t_1^*] \rightarrow_{x_1^* x_2^*} [t_2^*]$).

Note

More generally, instead of a shared type $[t^*]$, it suffices if the output type of $instr_1^*$ is a **subtype** of the input type of $instr_2^*$, since the subtype can always be weakened to its supertype by subsumption.

Inversely, valid instruction sequences can also freely be *decomposed*, that is, splitting them anywhere produces two instruction sequences that are both **valid**.

Theorem (Decomposition). If an instruction sequence $instr^*$ that is valid with type $[t_1^*] \rightarrow_{x^*} [t_2^*]$ (i.e., $C \vdash instr^* : [t_1^*] \rightarrow_{x^*} [t_2^*]$) is split into two instruction sequences $instr_1^*$ and $instr_2^*$ at any point (i.e., $instr^* = instr_1^* instr_2^*$), then these are separately valid with some types $[t_1^*] \rightarrow_{x_1^*} [t^*]$ and $[t^*] \rightarrow_{x_2^*} [t_2^*]$, respectively (i.e., $C \vdash instr_1^* : [t_1^*] \rightarrow_{x_1^*} [t^*]$ and $C \vdash instr_2^* : [t^*] \rightarrow_{x_2^*} [t_2^*]$), where $x^* = x_1^* x_2^*$.

Note

This property holds because validation is required even for unreachable code. Without that, $instr_2^*$ might not be valid in isolation.

7.6 Validation Algorithm

The specification of WebAssembly **validation** is purely *declarative*. It describes the constraints that must be met by a **module** or **instruction** sequence to be valid.

This section sketches the skeleton of a sound and complete *algorithm* for effectively validating code, i.e., sequences of **instructions**. (Other aspects of validation are straightforward to implement.)

In fact, the algorithm is expressed over the flat sequence of opcodes as occurring in the **binary format**, and performs only a single pass over it. Consequently, it can be integrated directly into a decoder.

The algorithm is expressed in typed pseudo code whose semantics is intended to be self-explanatory.

7.6.1 Data Structures

Types

Value types are representable as sets of enumerations:

```
type num_type = I32 | I64 | F32 | F64
type vec_type = V128
type heap_type =
  Any | Eq | I31 | Struct | Array | None |
  Func | Nofunc | Exn | Noexn | Extern | Noextern | Bot |
  Def(def : def_type)
type ref_type = Ref(heap : heap_type, null : bool)
type val_type = num_type | vec_type | ref_type | Bot

func is_num(t : val_type) : bool =
  return t = I32 || t = I64 || t = F32 || t = F64 || t = Bot

func is_vec(t : val_type) : bool =
  return t = V128 || t = Bot

func is_ref(t : val_type) : bool =
  return not (is_num t || is_vec t) || t = Bot
```

Similarly, `defined types` `def_type` can be represented:

```
type pack_type = I8 | I16
type field_type = Field(val : val_type | pack_type, mut : bool)

type struct_type = Struct(fields : list(field_type))
type array_type = Array(fields : field_type)
type func_type = Func(params : list(val_type), results : list(val_type))
type comp_type = struct_type | array_type | func_type

type sub_type = Sub(super : list(def_type), body : comp_type, final : bool)
type rec_type = Rec(types : list(sub_type))

type def_type = Def(rec : rec_type, proj : int32)

func unpack_field(t : field_type) : val_type =
  if (it = I8 || t = I16) return I32
  return t

func expand_def(t : def_type) : comp_type =
  return t.rec.types[t.proj].body
```

These representations assume that all types have been `closed` by `substituting` all `type indices` (in `concrete heap types` and in `sub types`) with their respective `defined types`. This includes *recursive* references to enclosing `defined types`, such that type representations form graphs and may be *cyclic* for *recursive types*.

We assume that all types have been *canonicalized*, such that equality on two type representations holds if and only if their *closures* are syntactically equivalent, making it a constant-time check.

Note

For the purpose of type canonicalization, recursive references from a `heap type` to an enclosing `recursive type` (i.e., forward edges in the graph that form a cycle) need to be distinguished from references to previously defined types. However, this distinction does not otherwise affect validation, so is ignored here. In the graph representation, all recursive types are effectively infinitely `unrolled`.

We further assume that [validation](#) and [subtyping](#) checks are defined on value types, as well as a few auxiliary functions on composite types:

```
func validate_val_type(t : val_type)
func validate_ref_type(t : ref_type)

func matches_val(t1 : val_type, t2 : val_type) : bool
func matches_ref(t1 : val_type, t2 : val_type) : bool

func is_func(t : comp_type) : bool
func is_struct(t : comp_type) : bool
func is_array(t : comp_type) : bool
```

Finally, the following function computes the least precise supertype of a given [heap type](#) (its corresponding top type):

```
func top_heap_type(t : heap_type) : heap_type =
  switch (t)
  case (Any | Eq | I31 | Struct | Array | None)
    return Any
  case (Func | Nofunc)
    return Func
  case (Extern | Noextern)
    return Extern
  case (Def(dt))
    switch (dt.rec.types[dt.proj].body)
    case (Struct(_) | Array(_))
      return Any
    case (Func(_))
      return Func
  case (Bot)
    raise CannotOccurInSource
```

Context

Validation requires a [context](#) for checking uses of [indices](#). For the purpose of presenting the algorithm, it is maintained in a set of global variables:

```
var return_type : list(val_type)
var types : array(def_type)
var locals : array(val_type)
var locals_init : array(bool)
var globals : array(global_type)
var funcs : array(func_type)
var tables : array(table_type)
var mems : array(mem_type)
```

This assumes suitable representations for the various [types](#) besides `val_type`, which are omitted here.

For locals, there is an additional array recording the initialization status of each local.

Stacks

The algorithm uses three separate stacks: the *value stack*, the *control stack*, and the *initialization stack*. The value stack tracks the [types](#) of operand values on the [stack](#). The control stack tracks surrounding [structured control instructions](#) and their associated [blocks](#). The initialization stack records all [locals](#) that have been initialized since the beginning of the function.

```

type val_stack = stack(val_type)
type init_stack = stack(u32)

type ctrl_stack = stack(ctrl_frame)
type ctrl_frame = {
  opcode : opcode
  start_types : list(val_type)
  end_types : list(val_type)
  val_height : nat
  init_height : nat
  unreachable : bool
}

```

For each entered block, the control stack records a *control frame* with the originating opcode, the types on the top of the operand stack at the start and end of the block (used to check its result as well as branches), the height of the operand stack at the start of the block (used to check that operands do not underflow the current block), the height of the initialization stack at the start of the block (used to reset initialization status at the end of the block), and a flag recording whether the remainder of the block is unreachable (used to handle [stack-polymorphic](#) typing after branches).

For the purpose of presenting the algorithm, these stacks are simply maintained as global variables:

```

var vals : val_stack
var inits : init_stack
var ctrls : ctrl_stack

```

However, these variables are not manipulated directly by the main checking function, but through a set of auxiliary functions:

```

func push_val(type : val_type) =
  vals.push(type)

func pop_val() : val_type =
  if (vals.size() = ctrls[0].height && ctrls[0].unreachable) return Bot
  error_if(vals.size() = ctrls[0].height)
  return vals.pop()

func pop_val(expect : val_type) : val_type =
  let actual = pop_val()
  error_if(not matches_val(actual, expect))
  return actual

func pop_num() : num_type | Bot =
  let actual = pop_val()
  error_if(not is_num(actual))
  return actual

func pop_ref() : ref_type =
  let actual = pop_val()
  error_if(not is_ref(actual))
  if (actual = Bot) return Ref(Bot, false)
  return actual

func push_vals(types : list(val_type)) = foreach (t in types) push_val(t)
func pop_vals(types : list(val_type)) : list(val_type) =
  var popped := []
  foreach (t in reverse(types)) popped.prepend(pop_val(t))
  return popped

```

Pushing an operand value simply pushes the respective type to the value stack.

Popping an operand value checks that the value stack does not underflow the current block and then removes one type. But first, a special case is handled where the block contains no known values, but has been marked as unreachable. That can occur after an unconditional branch, when the stack is typed [polymorphically](#). In that case, the Bot type is returned, because that is a *principal* choice trivially satisfying all use constraints.

A second function for popping an operand value takes an expected type, which the actual operand type is checked against. The types may differ by subtyping, including the case where the actual type is Bot, and thereby matches unconditionally. The function returns the actual type popped from the stack.

Finally, there are accumulative functions for pushing or popping multiple operand types.

Note

The notation `stack[i]` is meant to index the stack from the top, so that, e.g., `ctrls[0]` accesses the element pushed last.

The initialization stack and the initialization status of locals is manipulated through the following functions:

```
func get_local(idx : u32) =
  error_if(not locals_init[idx])

func set_local(idx : u32) =
  if (not locals_init[idx])
    inits.push(idx)
    locals_init[idx] := true

func reset_locals(height : nat) =
  while (inits.size() > height)
    locals_init[inits.pop()] := false
```

Getting a local verifies that it is known to be initialized. When a local is set that was not set already, then its initialization status is updated and the change is recorded in the initialization stack. Thus, the initialization status of all locals can be reset to a previous state by denoting a specific height in the initialization stack.

The size of the initialization stack is bounded by the number of (non-defaultable) locals in a function, so can be preallocated by an algorithm.

The control stack is likewise manipulated through auxiliary functions:

```
func push_ctrl(opcode : opcode, in : list(val_type), out : list(val_type)) =
  let frame = ctrl_frame(opcode, in, out, vals.size(), inits.size(), false)
  ctrls.push(frame)
  push_vals(in)

func pop_ctrl() : ctrl_frame =
  error_if(ctrls.is_empty())
  let frame = ctrls[0]
  pop_vals(frame.end_types)
  error_if(vals.size() != frame.val_height)
  reset_locals(frame.init_height)
  ctrls.pop()
  return frame

func label_types(frame : ctrl_frame) : list(val_types) =
  return (if (frame.opcode = loop) frame.start_types else frame.end_types)

func unreachable() =
```

(continues on next page)

(continued from previous page)

```
vals.resize(ctrls[0].height)
ctrls[0].unreachable := true
```

Pushing a control frame takes the types of the label and result values. It allocates a new frame record recording them along with the current height of the operand stack and marks the block as reachable.

Popping a frame first checks that the control stack is not empty. It then verifies that the operand stack contains the right types of values expected at the end of the exited block and pops them off the operand stack. Afterwards, it checks that the stack has shrunk back to its initial height. Finally, it undoes all changes to the initialization status of locals that happen inside the block.

The type of the [label](#) associated with a control frame is either that of the stack at the start or the end of the frame, determined by the opcode that it originates from.

Finally, the current frame can be marked as unreachable. In that case, all existing operand types are purged from the value stack, in order to allow for the [stack-polymorphism](#) logic in `pop_val` to take effect. Because every function has an implicit outermost label that corresponds to an implicit block frame, it is an invariant of the validation algorithm that there always is at least one frame on the control stack when validating an instruction, and hence, `ctrls[0]` is always defined.

Note

Even with the unreachable flag set, consecutive operands are still pushed to and popped from the operand stack. That is necessary to detect invalid [examples](#) like `(unreachable (i32.const) i64.add)`. However, a polymorphic stack cannot underflow, but instead generates Bot types as needed.

7.6.2 Validation of Opcode Sequences

The following function shows the validation of a number of representative instructions that manipulate the stack. Other instructions are checked in a similar manner.

```
func validate(opcode) =
  switch (opcode)
  case (i32.add)
    pop_val(I32)
    pop_val(I32)
    push_val(I32)

  case (drop)
    pop_val()

  case (select)
    pop_val(I32)
    let t1 = pop_val()
    let t2 = pop_val()
    error_if(not (is_num(t1) && is_num(t2) || is_vec(t1) && is_vec(t2)))
    error_if(t1 != t2 && t1 != Bot && t2 != Bot)
    push_val(if (t1 == Bot) t2 else t1)

  case (select t)
    pop_val(I32)
    pop_val(t)
    pop_val(t)
    push_val(t)

  case (ref.is_null)
    pop_ref()
```

(continues on next page)

(continued from previous page)

```

    push_val(I32)

    case (ref.as_non_null)
      let rt = pop_ref()
      push_val(Ref(rt.heap, false))

    case (ref.test rt)
      validate_ref_type(rt)
      pop_val(Ref(top_heap_type(rt), true))
      push_val(I32)

    case (local.get x)
      get_local(x)
      push_val(locals[x])

    case (local.set x)
      pop_val(locals[x])
      set_local(x)

    case (unreachable)
      unreachable()

    case (block t1*->t2*)
      pop_vals([t1*])
      push_ctrl(block, [t1*], [t2*])

    case (loop t1*->t2*)
      pop_vals([t1*])
      push_ctrl(loop, [t1*], [t2*])

    case (if t1*->t2*)
      pop_val(I32)
      pop_vals([t1*])
      push_ctrl(if, [t1*], [t2*])

    case (end)
      let frame = pop_ctrl()
      push_vals(frame.end_types)

    case (else)
      let frame = pop_ctrl()
      error_if(frame.opcode != if)
      push_ctrl(else, frame.start_types, frame.end_types)

    case (br n)
      error_if(ctrls.size() < n)
      pop_vals(label_types(ctrls[n]))
      unreachable()

    case (br_if n)
      error_if(ctrls.size() < n)
      pop_val(I32)
      pop_vals(label_types(ctrls[n]))
      push_vals(label_types(ctrls[n]))

    case (br_table n* m)

```

(continues on next page)

(continued from previous page)

```

    pop_val(I32)
    error_if(ctrls.size() < m)
    let arity = label_types(ctrls[m]).size()
    foreach (n in n*)
        error_if(ctrls.size() < n)
        error_if(label_types(ctrls[n]).size() != arity)
        push_vals(pop_vals(label_types(ctrls[n])))
    pop_vals(label_types(ctrls[m]))
    unreachable()

case (br_on_null n)
    error_if(ctrls.size() < n)
    let rt = pop_ref()
    pop_vals(label_types(ctrls[n]))
    push_vals(label_types(ctrls[n]))
    push_val(Ref(rt.heap, false))

case (br_on_cast n rt1 rt2)
    validate_ref_type(rt1)
    validate_ref_type(rt2)
    pop_val(rt1)

    pop_vals(label_types(ctrls[n]))
    push_vals(label_types(ctrls[n]))
    pop_val(rt2)
    push_val(diff_ref_type(rt2, rt1))

case (return)
    pop_vals(return_types)
    unreachable()

case (call_ref x)
    let t = expand_def(types[x])
    error_if(not is_func(t))
    pop_vals(t.params)
    pop_val(Ref(Def(types[x])))
    push_vals(t.results)

case (return_call_ref x)
    let t = expand_def(types[x])
    error_if(not is_func(t))
    pop_vals(t.params)
    pop_val(Ref(Def(types[x])))
    error_if(t.results.len() != return_types.len())
    push_vals(t.results)
    pop_vals(return_types)
    unreachable()

case (struct.new x)
    let t = expand_def(types[x])
    error_if(not is_struct(t))
    for (ti in reverse(t.fields))
        pop_val(unpack_field(ti))
    push_val(Ref(Def(types[x])))

case (struct.set x n)

```

(continues on next page)

(continued from previous page)

```

let t = expand_def(types[x])
error_if(not is_struct(t) || n >= t.fields.len())
pop_val(Ref(Def(types[x])))
pop_val(unpack_field(st.fields[n]))

case (throw x)
  pop_vals(tags[x].type.params)
  unreachable()

case (try_table t1*->t2* handler*)
  pop_vals([t1*])
  foreach (handler in handler*)
    error_if(ctrls.size() < handler.label)
    push_ctrl(catch, [], label_types(ctrls[handler.label]))
    switch (handler.clause)
      case (catch x)
        push_vals(tags[x].type.params)
      case (catch_ref x)
        push_vals(tags[x].type.params)
        push_val(Exnref)
      case (catch_all)
        skip
      case (catch_all_ref)
        push_val(Exnref)
    pop_ctrl()
  push_ctrl(try_table, [t1*], [t2*])

```

Note

It is an invariant under the current WebAssembly instruction set that an operand of `Bot` type is never duplicated on the stack. This would change if the language were extended with stack instructions like `dup`. Under such an extension, the above algorithm would need to be refined by replacing the `Bot` type with proper *type variables* to ensure that all uses are consistent.

7.7 Custom Sections and Annotations

This appendix defines dedicated [custom sections](#) for WebAssembly's [binary format](#) and [annotations](#) for the text format. Such sections or annotations do not contribute to, or otherwise affect, the WebAssembly semantics, and may be ignored by an implementation. However, they provide useful meta data that implementations can make use of to improve user experience or take compilation hints.

7.7.1 Name Section

The *name section* is a [custom section](#) whose name string is itself 'name'. The name section should appear only once in a module, and only after the [data section](#).

The purpose of this section is to attach printable names to definitions in a module, which e.g. can be used by a debugger or when parts of the module are to be rendered in [text form](#).

Note

All [names](#) are represented in [Unicode](#)⁵⁶ encoded in UTF-8. Names need not be unique.

⁵⁶ <https://www.unicode.org/versions/latest/>

Subsections

The `data` of a name section consists of a sequence of *subsections*. Each subsection consists of a

- a one-byte subsection *id*,
- the *u32* *size* of the contents, in bytes,
- the actual *contents*, whose structure is dependent on the subsection id.

```

namesec          ::= section0(namedata)
namedata         ::= n:name (if n = 'name')
                   modulenamesubsec?
                   funcnamesubsec?
                   localnamesubsec?
                   typenamesubsec?
                   fieldnamesubsec?
                   tagnamesubsec?
namesubsectionN(B) ::= N:byte size:u32 B (if size = ||B||)

```

The following subsection ids are used:

Id	Subsection
0	module name
1	function names
2	local names
4	type names
10	field names
11	tag names

Each subsection may occur at most once, and in order of increasing id.

Name Maps

A *name map* assigns *names* to *indices* in a given *index space*. It consists of a *list* of index/name pairs in order of increasing index value. Each index must be unique, but the assigned names need not be.

```

namemap          ::= list(nameassoc)
nameassoc        ::= idx name

```

An *indirect name map* assigns *names* to a two-dimensional *index space*, where secondary indices are *grouped* by primary indices. It consists of a list of primary index/name map pairs in order of increasing index value, where each name map in turn maps secondary indices to names. Each primary index must be unique, and likewise each secondary index per individual name map.

```

indirectnamemap  ::= list(indirectnameassoc)
indirectnameassoc ::= idx namemap

```

Module Names

The *module name subsection* has the id 0. It simply consists of a single *name* that is assigned to the module itself.

```

modulenamesubsec ::= namesubsection0(name)

```

Function Names

The *function name subsection* has the id 1. It consists of a *name map* assigning function names to *function indices*.

```

funcnamesubsec  ::= namesubsection1(namemap)

```

Local Names

The *local name subsection* has the id 2. It consists of an [indirect name map](#) assigning local names to [local indices](#) grouped by [function indices](#).

```
localnamesubsec ::= namesubsection2(indirectnamemap)
```

Type Names

The *type name subsection* has the id 4. It consists of a [name map](#) assigning type names to [type indices](#).

```
typenamesubsec ::= namesubsection4(namemap)
```

Field Names

The *field name subsection* has the id 10. It consists of an [indirect name map](#) assigning field names to [field indices](#) grouped by the [type indices](#) of their respective [structure types](#).

```
fieldnamesubsec ::= namesubsection10(indirectnamemap)
```

Tag Names

The *tag name subsection* has the id 11. It consists of a [name map](#) assigning tag names to [tag indices](#).

```
tagnamesubsec ::= namesubsection11(namemap)
```

7.7.2 Name Annotations

Name annotations are the textual analogue to the [name section](#) and provide a textual representation for it. Consequently, their id is `@name`.

Analogous to the name section, name annotations are allowed on [modules](#), [functions](#), and [locals](#) (including [parameters](#)). They can be placed where the text format allows binding occurrences of respective [identifiers](#). If both an identifier and a name annotation are given, the annotation is expected *after* the identifier. In that case, the annotation takes precedence over the identifier as a textual representation of the binding's name. At most one name annotation may be given per binding.

All name annotations have the following format:

```
nameannot ::= '(@name' string ')
```

Note

All name annotations can be arbitrary UTF-8 [strings](#). Names need not be unique.

Module Names

A *module name annotation* must be placed on a [module](#) definition, directly after the 'module' keyword, or if present, after the following module [identifier](#).

```
modulenameannot ::= nameannot
```

Function Names

A *function name annotation* must be placed on a [function](#) definition or function [import](#), directly after the ‘func’ keyword, or if present, after the following function [identifier](#) or.

```
funcnameannot ::= nameannot
```

Parameter Names

A *parameter name annotation* must be placed on a [parameter](#) declaration, directly after the ‘param’ keyword, or if present, after the following parameter [identifier](#). It may only be placed on a declaration that declares exactly one parameter.

```
paramnameannot ::= nameannot
```

Local Names

A *local name annotation* must be placed on a [local](#) declaration, directly after the ‘local’ keyword, or if present, after the following local [identifier](#). It may only be placed on a declaration that declares exactly one local.

```
localnameannot ::= nameannot
```

Type Names

A *type name annotation* must be placed on a [type](#) declaration, directly after the ‘type’ keyword, or if present, after the following type [identifier](#).

```
typenameannot ::= nameannot
```

Field Names

A *field name annotation* must be placed on the field of a [structure type](#), directly after the ‘field’ keyword, or if present, after the following field [identifier](#). It may only be placed on a declaration that declares exactly one field.

```
fieldnameannot ::= nameannot
```

Tag Names

A *tag name annotation* must be placed on a [tag declaration](#) or tag [import](#), directly after the ‘tag’ keyword, or if present, after the following tag [identifier](#).

```
tagnameannot ::= nameannot
```

7.7.3 Custom Annotations

Custom annotations are a generic textual representation for any [custom section](#). Their id is @custom. By generating custom annotations, tools converting between [binary format](#) and [text format](#) can maintain and round-trip the content of custom sections even when they do not recognize them.

Custom annotations must be placed inside a [module](#) definition. They must occur anywhere after the ‘module’ keyword, or if present, after the following module [identifier](#). They must not be nested into other constructs.

```

customannot ::= '(@custom' string customplace? datastring ')'
customplace ::= '(' 'before' 'first' ')',
                '(' 'before' sec ')',
                '(' 'after' sec ')',
                '(' 'after' 'last' ')',
sec          ::= 'type'
                | 'import'
                | 'func'
                | 'table'
                | 'memory'
                | 'global'
                | 'export'
                | 'start'
                | 'elem'
                | 'code'
                | 'data'
                | 'datacount'

```

The first [string](#) in a custom annotation denotes the name of the custom section it represents. The remaining strings collectively represent the section’s payload data, written as a [data string](#), which can be split up into a possibly empty sequence of individual string literals (similar to [data segments](#)).

An arbitrary number of custom annotations (even of the same name) may occur in a module, each defining a separate custom section when converting to [binary format](#). Placement of the sections in the binary can be customized via explicit *placement* directives, that position them either directly before or directly after a known section. That section must exist and be non-empty in the binary encoding of the annotated module. The placements (*before first*) and (*after last*) denote virtual sections before the first and after the last known section, respectively. When the placement directive is omitted, it defaults to (*after last*).

If multiple placement directives appear for the same position, then the sections are all placed there, in order of their appearance in the text. For this purpose, the position *after* a section is considered different from the position *before* the consecutive section, and the former occurs before the latter.

Note

Future versions of WebAssembly may introduce additional sections between others or at the beginning or end of a module. Using *first* and *last* guarantees that placement will still go before or after any future section, respectively.

If a custom section with a specific section id is given as well as annotations representing the same custom section (e.g., [@name annotations](#) as well as a [@custom](#) annotation for a [name section](#)), then two sections are assumed to be created. Their relative placement will depend on the placement directive given for the [@custom](#) annotation as well as the implicit placement requirements of the custom section, which are applied to the other annotation.

Note

For example, the following module,

```

(module
  (@custom "A" "aaa")
  (type $t (func))
  (@custom "B" (after func) "bbb")
  (@custom "C" (before func) "ccc")
  (@custom "D" (after last) "ddd")
  (table 10 funcref)
  (func (type $t))

```

```
(@custom "E" (after import) "eee")
(@custom "F" (before type) "fff")
(@custom "G" (after data) "ggg")
(@custom "H" (after code) "hhh")
(@custom "I" (after func) "iii")
(@custom "J" (before func) "jjj")
(@custom "K" (before first) "kkk")
)
```

will result in the following section ordering:

```
custom section "K"
custom section "F"
type section
custom section "E"
custom section "C"
custom section "J"
function section
custom section "B"
custom section "I"
table section
code section
custom section "H"
custom section "G"
custom section "A"
custom section "D"
```

7.8 Change History

Since the original release 1.0 of the WebAssembly specification, a number of proposals for extensions have been integrated. The following sections provide an overview of what has changed.

All present and future versions of WebAssembly are intended to be *backwards-compatible* with all previous versions. Concretely:

1. All syntactically well-formed (in [binary](#) or [text](#) format) and [valid](#) modules remain well-formed and valid with an equivalent [module type](#) (or a subtype).

Note

This allows previously malformed or invalid modules to become legal, e.g., by adding new features or by relaxing typing rules.

It also allows reclassifying previously malformed modules as well-formed but invalid, or vice versa.

And it allows refining the typing of [imports](#) and [exports](#), such that previously unlinkable modules become linkable.

Historically, minor breaking changes to the *text format* have been allowed that turned previously possible valid modules invalid, as long as they were unlikely to occur in practice.

2. All non-[trapping executions](#) of a valid program retain their behaviour with an equivalent set of possible [results](#) (or a non-empty subset).

Note

This allows previously malformed or invalid programs to become executable.

It also allows program executions that previously trapped to execute successfully, although the intention is to only exercise this where the possibility of such an extension has been previously noted.

And it allows reducing the set of observable behaviours of a program execution, e.g., by reducing non-determinism.

In a program linking prior modules with modules using new features, a prior module may encounter new behaviours, e.g., new forms of control flow or side effects when calling into a latter module.

In addition, future versions of WebAssembly will not allocate the `opcode 0xFF` to represent an instruction or instruction prefix.

7.8.1 Release 2.0

Sign Extension Instructions

Added new numeric instructions for performing sign extension within integer representations.⁵⁷

- New `numeric instructions`:
 - `inn.extendN_s`

Non-trapping Float-to-Int Conversions

Added new conversion instructions that avoid trapping when converting a floating-point number to an integer.⁵⁸

- New `numeric instructions`:
 - `inn.trunc_sat_fmm_sx`

Multiple Values

Generalized the result type of blocks and functions to allow for multiple values; in addition, introduced the ability to have block parameters.⁵⁹

- `Function types` allow more than one result
- `Block types` can be arbitrary function types

Reference Types

Added `funcref` and `externref` as new value types and respective instructions.⁶⁰

- New `reference value types`:
 - `funcref`
 - `externref`
- New `reference instructions`:
 - `ref.null`
 - `ref.func`
 - `ref.is_null`
- Extended `parametric instruction`:
 - `select` with optional type immediate
- New `declarative form of element segment`

⁵⁷ <https://github.com/WebAssembly/spec/tree/main/proposals/sign-extension-ops/>

⁵⁸ <https://github.com/WebAssembly/spec/tree/main/proposals/nontrapping-float-to-int-conversion/>

⁵⁹ <https://github.com/WebAssembly/spec/tree/main/proposals/multi-value/>

⁶⁰ <https://github.com/WebAssembly/spec/tree/main/proposals/reference-types/>

Table Instructions

Added instructions to directly access and modify tables.^{Page 278, 60}

- Table types allow any reference type as element type
- New table instructions:
 - table.get
 - table.set
 - table.size
 - table.grow

Multiple Tables

Added the ability to use multiple tables per module.^{Page 278, 60}

- Modules may
 - define multiple tables
 - import multiple tables
 - export multiple tables
- Table instructions take a table index immediate:
 - table.get
 - table.set
 - table.size
 - table.grow
 - call_indirect
- Element segments take a table index

Bulk Memory and Table Instructions

Added instructions that modify ranges of memory or table entries.^{Page 278, 6061}

- New memory instructions:
 - memory.fill
 - memory.init
 - memory.copy
 - data.drop
- New table instructions:
 - table.fill
 - table.init
 - table.copy
 - elem.drop
- New passive form of data segment
- New passive form of element segment
- New data count section in binary format
- Active data and element segments boundaries are no longer checked at compile time but may trap instead

⁶¹ <https://github.com/WebAssembly/spec/tree/main/proposals/bulk-memory-operations/>

Vector Instructions

Added vector type and instructions that manipulate multiple numeric values in parallel (also known as *SIMD*, single instruction multiple data)⁶²

- New **value type**:
 - `v128`
- New **memory instructions**:
 - `v128.load`
 - `v128.loadN \times Msx`
 - `v128.loadN_zero`
 - `v128.loadN_splat`
 - `v128.loadN_lane`
 - `v128.store`
 - `v128.storeN_lane`
- New constant **vector instruction**:
 - `v128.const`
- New unary **vector instructions**:
 - `v128.not`
 - `iN \times M.abs`
 - `iN \times M.neg`
 - `i8 \times 16.popcnt`
 - `fN \times M.abs`
 - `fN \times M.neg`
 - `fN \times M.sqrt`
 - `fN \times M.ceil`
 - `fN \times M.floor`
 - `fN \times M.trunc`
 - `fN \times M.nearest`
- New binary **vector instructions**:
 - `v128.and`
 - `v128.andnot`
 - `v128.or`
 - `v128.xor`
 - `iN \times M.add`
 - `iN \times M.sub`
 - `iN \times M.mul`
 - `iN \times M.add_satsx`
 - `iN \times M.sub_satsx`
 - `iN \times M.minsx`

⁶² <https://github.com/WebAssembly/spec/tree/main/proposals/simd/>

- *iNxM.max_sx*
- *iNxM.shl*
- *iNxM.shr_sx*
- *fNxM.add*
- *fNxM.sub*
- *fNxM.mul*
- *fNxM.div*
- *i16x8.extadd_pairwise_i8x16_sx*
- *i32x4.extadd_pairwise_i16x8_sx*
- *iNxM.extmul_half_iN'xM'_sx*
- *i16x8.q15mulr_sat_s*
- *i32x4.dot_i16x8_s*
- *i8x16.avgr_u*
- *i16x8.avgr_u*
- *fNxM.min*
- *fNxM.max*
- *fNxM.pmin*
- *fNxM.pmax*
- New ternary **vector instruction**:
 - *v128.bitselect*
- New test **vector instructions**:
 - *v128.any_true*
 - *iNxM.all_true*
- New relational **vector instructions**:
 - *iNxM.eq*
 - *iNxM.ne*
 - *iNxM.lt_sx*
 - *iNxM.gt_sx*
 - *iNxM.le_sx*
 - *iNxM.ge_sx*
 - *fNxM.eq*
 - *fNxM.ne*
 - *fNxM.lt*
 - *fNxM.gt*
 - *fNxM.le*
 - *fNxM.ge*
- New conversion **vector instructions**:
 - *i32x4.trunc_sat_f32x4_sx*
 - *i32x4.trunc_sat_f64x2_sx_zero*

- `f32x4.convert_i32x4_sx`
- `f32x4.demote_f64x2_zero`
- `f64x2.convert_low_i32x4_sx`
- `f64x2.promote_low_f32x4`
- New lane access [vector instructions](#):
 - `iNxM.extract_lane_sx`[?]
 - `iNxM.replace_lane`
 - `fNxM.extract_lane`
 - `fNxM.replace_lane`
- New lane splitting/combining [vector instructions](#):
 - `iNxM.extend_half_iN'xM'_sx`
 - `i8x16.narrow_i16x8_sx`
 - `i16x8.narrow_i32x4_sx`
- New byte reordering [vector instructions](#):
 - `i8x16.shuffle`
 - `i8x16.swizzle`
- New injection/projection [vector instructions](#):
 - `iNxM.splat`
 - `fNxM.splat`
 - `iNxM.bitmask`

7.8.2 Release 3.0

Extended Constant Expressions

Allowed basic numeric computations in constant expressions.⁶³

- Extended set of [constant instructions](#) with:
 - `inn.add`
 - `inn.sub`
 - `inn.mul`
 - `global.get` for any previously declared immutable [global](#)

Note

The [garbage collection](#) extension added further constant instructions.

Tail Calls

Added instructions to perform tail calls.⁶⁴

- New [control instructions](#):
 - `return_call`
 - `return_call_indirect`

⁶³ <https://github.com/WebAssembly/spec/tree/main/proposals/extended-const/>

⁶⁴ <https://github.com/WebAssembly/spec/tree/main/proposals/tail-call/>

Exception Handling

Added tag definitions, imports, and exports, and instructions to throw and catch exceptions⁶⁵

- Modules may
 - define tags
 - import tags
 - export tags
- New heap types:
 - `exn`
 - `noexn`
- New reference type short-hands:
 - `exnref`
 - `nullexnref`
- New control instructions:
 - `throw`
 - `throw_ref`
 - `try_table`
- New tag section in binary format.

Multiple Memories

Added the ability to use multiple memories per module.⁶⁶

- Modules may
 - define multiple memories
 - import multiple memories
 - export multiple memories
- Memory instructions take a memory index immediate:
 - `memory.size`
 - `memory.grow`
 - `memory.fill`
 - `memory.copy`
 - `memory.init`
 - `t.load`
 - `t.store`
 - `t.loadNsx`
 - `t.storeN`
 - `v128.loadNMsx`
 - `v128.loadNzero`
 - `v128.loadNsplat`
 - `v128.loadNlane`

⁶⁵ <https://github.com/WebAssembly/spec/tree/main/proposals/exception-handling/>

⁶⁶ <https://github.com/WebAssembly/spec/tree/main/proposals/multi-memory/>

- v128.storeN_lane
- Data segments take a memory index

64-bit Address Space

Added the ability to declare an i64 address type for tables and memories.⁶⁷

- Address types denote a subset of the integral number types
- Table types include an address type
- Memory types include an address type
- Operand types of table and memory instructions now depend on the subject's declared address type:
 - table.get
 - table.set
 - table.size
 - table.grow
 - table.fill
 - table.copy
 - table.init
 - memory.size
 - memory.grow
 - memory.fill
 - memory.copy
 - memory.init
 - t.load
 - t.store
 - t.loadN_sx
 - t.storeN
 - v128.loadNxM_sx
 - v128.loadN_zero
 - v128.loadN_splat
 - v128.loadN_lane
 - v128.storeN_lane

Typeful References

Added more precise types for references.⁶⁸

- New generalised form of reference types:
 - (ref null? *heaptypes*)
- New class of heap types:
 - func
 - extern

⁶⁷ <https://github.com/WebAssembly/spec/tree/main/proposals/memory64/>

⁶⁸ <https://github.com/WebAssembly/spec/tree/main/proposals/function-references/>

- *typeid*
- Basic subtyping on reference and value types
- New reference instructions:
 - `ref.as_non_null`
 - `br_on_null`
 - `br_on_non_null`
- New control instruction:
 - `call_ref`
- Refined typing of reference instruction:
 - `ref.func` with more precise result type
- Refined typing of local instructions and instruction sequences to track the initialization status of locals with non-defaultable type
- Refined decoding of active element segments with implicit element type and plain function indices (opcode 0) to produce non-null reference type.
- Extended table definitions with optional initializer expression

Garbage Collection

Added managed reference types.⁶⁹

- New forms of heap types:
 - `any`
 - `eq`
 - `i31`
 - `struct`
 - `array`
 - `none`
 - `nofunc`
 - `noextern`
- New reference type short-hands:
 - `anyref`
 - `eqref`
 - `i31ref`
 - `structref`
 - `arrayref`
 - `nullref`
 - `nullfuncref`
 - `nullexternref`
- New forms of type definitions:
 - `structure`
 - `array types`

⁶⁹ <https://github.com/WebAssembly/spec/tree/main/proposals/gc/>

- sub types
 - recursive types
- Enriched [subtyping](#) based on explicitly declared [sub types](#) and the new heap types
- New [generic reference instructions](#):
 - `ref.eq`
 - `ref.test`
 - `ref.cast`
 - `br_on_cast`
 - `br_on_cast_fail`
- New [reference instructions for unboxed scalars](#):
 - `ref.i31`
 - `i31.get_sx`
- New [reference instructions for structure types](#):
 - `struct.new`
 - `struct.new_default`
 - `struct.get_sx?`
 - `struct.set`
- New [reference instructions for array types](#):
 - `array.new`
 - `array.new_default`
 - `array.new_fixed`
 - `array.new_data`
 - `array.new_elem`
 - `array.get_sx?`
 - `array.set`
 - `array.len`
 - `array.fill`
 - `array.copy`
 - `array.init_data`
 - `array.init_elem`
- New [reference instructions for converting external types](#):
 - `any.convert_extern`
 - `extern.convert_any`
- Extended set of [constant instructions](#) with:
 - `ref.i31`
 - `struct.new`
 - `struct.new_default`
 - `array.new`
 - `array.new_default`

- `array.new_fixed`
- `any.convert_extern`
- `extern.convert_any`

Relaxed Vector Instructions

Added new *relaxed* vector instructions, whose behaviour is non-deterministic and implementation-dependent.⁷⁰

- New binary *vector instruction*:
 - `fNxM.relaxed_min`
 - `fNxM.relaxed_max`
 - `i16x8.relaxed_q15mulr_s`
 - `i16x8.relaxed_dot_i8x16_i7x16_s`
- New ternary *vector instruction*:
 - `fNxM.relaxed_madd`
 - `fNxM.relaxed_nmadd`
 - `iNxM.relaxed_laneselect`
 - `i32x4.relaxed_dot_i8x16_i7x16_add_s`
- New conversion *vector instructions*:
 - `i32x4.relaxed_trunc_f32x4_sx`
 - `i32x4.relaxed_trunc_f64x2_sx_zero`
- New byte reordering *vector instruction*:
 - `i8x16.relaxed_swizzle`

Profiles

Introduced the concept of *profile* for specifying language subsets.

- A new profile defining a *deterministic* mode of execution.

Custom Annotations

Added generic syntax for custom annotations in the text format, mirroring the role of custom sections in the binary format.⁷¹

- *Annotations* of the form ‘(`@id ...`)’ are allowed anywhere in the *text format*
- *Identifiers* can be escaped as ‘`@” ... ”`’ with arbitrary *names*
- Defined *name annotations* ‘(`@name ” ... ”`)’ for:
 - *module names*
 - *type names*
 - *function names*
 - *local names*
 - *field names*
- Defined *custom annotation* ‘(`@custom ” ... ”`)’ to represent arbitrary *custom sections* in the text format

⁷⁰ <https://github.com/WebAssembly/spec/tree/main/proposals/relaxed-simd/>

⁷¹ <https://github.com/WebAssembly/spec/tree/main/proposals/annotations/>

7.9 Index of Types

Category	Constructor	Binary Opcode
Type index	x	(positive number as s32 or u32)
Number type	$i32$	0x7F (-1 as s7)
Number type	$i64$	0x7E (-2 as s7)
Number type	$f32$	0x7D (-3 as s7)
Number type	$f64$	0x7C (-4 as s7)
Vector type	$v128$	0x7B (-5 as s7)
(reserved)		0x7A .. 0x79
Packed type	$i8$	0x78 (-8 as s7)
Packed type	$i16$	0x77 (-9 as s7)
(reserved)		0x78 .. 0x75
Heap type	<code>noexn</code>	0x74 (-14 as s7)
Heap type	<code>nofunc</code>	0x73 (-13 as s7)
Heap type	<code>noextern</code>	0x72 (-14 as s7)
Heap type	<code>none</code>	0x71 (-15 as s7)
Heap type	<code>func</code>	0x70 (-16 as s7)
Heap type	<code>extern</code>	0x6F (-17 as s7)
Heap type	<code>any</code>	0x6E (-18 as s7)
Heap type	<code>eq</code>	0x6D (-19 as s7)
Heap type	$i31$	0x6C (-20 as s7)
Heap type	<code>struct</code>	0x6B (-21 as s7)
Heap type	<code>array</code>	0x6A (-22 as s7)
Heap type	<code>exn</code>	0x69 (-23 as s7)
(reserved)		0x68 .. 0x65
Reference type	<code>ref</code>	0x64 (-28 as s7)
Reference type	<code>ref null</code>	0x63 (-29 as s7)
(reserved)		0x62 .. 0x61
Composite type	<code>func $[valtype^*] \rightarrow [valtype^*]$</code>	0x60 (-32 as s7)
Composite type	<code>struct $fieldtype^*$</code>	0x5F (-33 as s7)
Composite type	<code>array $fieldtype$</code>	0x5E (-34 as s7)
(reserved)		0x5D .. 0x51
Sub type	<code>sub $typeid^* comptype$</code>	0x50 (-48 as s7)
Sub type	<code>sub final $typeid^* comptype$</code>	0x4F (-49 as s7)
Recursive type	<code>rec $subtype^*$</code>	0x4E (-50 as s7)
(reserved)		0x4D .. 0x41
Result type	$[\epsilon]$	0x40 (-64 as s7)
Tag type	<code>$typeuse$</code>	(none)
Global type	<code>$mut valtype$</code>	(none)
Memory type	<code>$addrtype limits$</code>	(none)
Table type	<code>$addrtype limits reftype$</code>	(none)

7.10 Index of Instructions

Instruction	Binary Opcode	Type	Validation	Execution
<code>unreachable</code>	0x00	$[t_1^*] \rightarrow [t_2^*]$	validation	execution
<code>nop</code>	0x01	$[] \rightarrow []$	validation	execution
<code>block bt</code>	0x02	$[t_1^*] \rightarrow [t_2^*]$	validation	execution
<code>loop bt</code>	0x03	$[t_1^*] \rightarrow [t_2^*]$	validation	execution
<code>if bt</code>	0x04	$[t_1^* i32] \rightarrow [t_2^*]$	validation	execution
<code>else</code>	0x05

(reserved)	0xFF			

Note

Multi-byte opcodes are given with the shortest possible encoding in the table. However, what is following the first byte is actually a [u32](#) with variable-length encoding and consequently has multiple possible representations.

7.11 Index of Semantic Rules

7.11.1 Well-formedness of Types

Construct	Judgement
Numeric type	$C \vdash \text{numtype} : \text{ok}$
Vector type	$C \vdash \text{vectype} : \text{ok}$
Heap type	$C \vdash \text{heapttype} : \text{ok}$
Reference type	$C \vdash \text{reftype} : \text{ok}$
Value type	$C \vdash \text{valtype} : \text{ok}$
Packed type	$C \vdash \text{packtype} : \text{ok}$
Storage type	$C \vdash \text{storagetype} : \text{ok}$
Field type	$C \vdash \text{fieldtype} : \text{ok}$
Result type	$C \vdash \text{resulttype} : \text{ok}$
Instruction type	$C \vdash \text{instrtype} : \text{ok}$
Composite type	$C \vdash \text{comptype} : \text{ok}$
Sub type	$C \vdash \text{subtype} : \text{ok}$
Recursive type	$C \vdash \text{rectype} : \text{ok}$
Defined type	$C \vdash \text{deftype} : \text{ok}$
Block type	$C \vdash \text{blocktype} : \text{instrtype}$
Tag type	$C \vdash \text{tagtype} : \text{ok}$
Global type	$C \vdash \text{globaltype} : \text{ok}$
Memory type	$C \vdash \text{memtype} : \text{ok}$
Table type	$C \vdash \text{tabletype} : \text{ok}$
External type	$C \vdash \text{externtype} : \text{ok}$
Type definitions	$C \vdash \text{type}^* : \text{ok}$

7.11.2 Typing of Static Constructs

Construct	Judgement
Instruction	$S; C \vdash \text{instr} : \text{instrtype}$
Instruction sequence	$S; C \vdash \text{instr}^* : \text{instrtype}$
Catch clause	$C \vdash \text{catch} : \text{ok}$
Expression	$C \vdash \text{expr} : \text{resulttype}$
Limits	$C \vdash \text{limits} : k$
Tag	$C \vdash \text{tag} : \text{tagtype}$
Global	$C \vdash \text{global} : \text{globaltype}$
Memory	$C \vdash \text{mem} : \text{memtype}$
Table	$C \vdash \text{table} : \text{tabletype}$
Function	$C \vdash \text{func} : \text{deftype}$
Local	$C \vdash \text{local} : \text{localtype}$
Element segment	$C \vdash \text{elem} : \text{reftype}$
Element mode	$C \vdash \text{elemmode} : \text{reftype}$
Data segment	$C \vdash \text{data} : \text{ok}$
Data mode	$C \vdash \text{datamode} : \text{ok}$
Start function	$C \vdash \text{start} : \text{ok}$
Import	$C \vdash \text{import} : \text{externtype}$
Export	$C \vdash \text{export} : \text{externtype}$
Module	$\vdash \text{module} : \text{externtype}^* \rightarrow \text{externtype}^*$

7.11.3 Typing of Runtime Constructs

Construct	Judgement
Value	$S \vdash val : valtype$
Result	$S \vdash result : resulttype$
Packed value	$S \vdash packval : packtype$
Field value	$S \vdash fieldval : storagetype$
External address	$S \vdash externaddr : externtype$
Tag instance	$S \vdash taginst : tagtype$
Global instance	$S \vdash globalinst : globaltype$
Memory instance	$S \vdash meminst : memtype$
Table instance	$S \vdash tableinst : tabletype$
Function instance	$S \vdash funcinst : deftype$
Data instance	$S \vdash datainst : ok$
Element instance	$S \vdash eleminst : t$
Structure instance	$S \vdash structinst : ok$
Array instance	$S \vdash arrayinst : ok$
Export instance	$S \vdash exportinst : ok$
Module instance	$S \vdash moduleinst : C$
Store	$\vdash store : ok$
Configuration	$\vdash config : [t^*]$
Thread	$S; resulttype^? \vdash thread : resulttype$
Frame	$S \vdash frame : C$

7.11.4 Constantness

Construct	Judgement
Constant expression	$C \vdash exprconst$
Constant instruction	$C \vdash instrconst$

7.11.5 Matching

Construct	Judgement
Number type	$C \vdash numtype_1 \leq numtype_2$
Vector type	$C \vdash vectype_1 \leq vectype_2$
Heap type	$C \vdash heaptypes_1 \leq heaptypes_2$
Reference type	$C \vdash reftype_1 \leq reftype_2$
Value type	$C \vdash valtype_1 \leq valtype_2$
Packed type	$C \vdash packtype_1 \leq packtype_2$
Storage type	$C \vdash storagetype_1 \leq storagetype_2$
Field type	$C \vdash fieldtype_1 \leq fieldtype_2$
Result type	$C \vdash resulttype_1 \leq resulttype_2$
Instruction type	$C \vdash instrtype_1 \leq instrtype_2$
Composite type	$C \vdash comptype_1 \leq comptype_2$
Defined type	$C \vdash deftype_1 \leq deftype_2$
Limits	$C \vdash limits_1 \leq limits_2$
Tag type	$C \vdash tagtype_1 \leq tagtype_2$
Global type	$C \vdash globaltype_1 \leq globaltype_2$
Memory type	$C \vdash memtype_1 \leq memtype_2$
Table type	$C \vdash tabletype_1 \leq tabletype_2$
External type	$C \vdash externtype_1 \leq externtype_2$

7.11.6 Store Extension

Construct	Judgement
Tag instance	$\vdash \text{taginst}_1 \preceq \text{taginst}_2$
Global instance	$\vdash \text{globalinst}_1 \preceq \text{globalinst}_2$
Memory instance	$\vdash \text{meminst}_1 \preceq \text{meminst}_2$
Table instance	$\vdash \text{tableinst}_1 \preceq \text{tableinst}_2$
Function instance	$\vdash \text{funcinst}_1 \preceq \text{funcinst}_2$
Data instance	$\vdash \text{datainst}_1 \preceq \text{datainst}_2$
Element instance	$\vdash \text{eleminst}_1 \preceq \text{eleminst}_2$
Structure instance	$\vdash \text{structinst}_1 \preceq \text{structinst}_2$
Array instance	$\vdash \text{arrayinst}_1 \preceq \text{arrayinst}_2$
Store	$\vdash \text{store}_1 \preceq \text{store}_2$

7.11.7 Execution

Construct	Judgement
Instruction	$S; F; \text{instr}^* \hookrightarrow S'; F'; \text{instr}'^*$
Expression	$S; F; \text{expr} \hookrightarrow S'; F'; \text{expr}'$
